*G*-space basics: (*G*: always compact Lie group here)

- *G*-points:  $G/H$  ( $H < G$  closed subgroup)

$(H)$ : conjugate classes

Orbit type:  $(H)$  or  $(G/H)$ , we choose the later

- The only *G*-equivariant maps between *G*-points:

$$G/H \rightarrow G/K$$

are surjective ones for  $(H) < (K)$ .

This gives a partial order among types.

- “Good”  $G$ -spaces are  $G$ -CW-complexes:  
 $G$ -manifolds are good, due to Illman (1983).

Conclusion

\*\*\*\*\*

- *G*-equivariant cohomology of *M* is defined as (Borel)

$$H_G^*(M) = H^*(M \times_G EG)$$

where  $EG \rightarrow BG$  is a classifying space for *G*-principal bundles.

- H. Cartan introduced “the equivariant de Rham differential forms”

$$(\Omega^*(M) \otimes W(\mathfrak{g}))^G$$

and equivariant exterior derivative, and showed that this gives the same cohomology up to  $\mathbb{Z}_2$ -grading when the *G*-action is locally free.

- $G$ -equivariant cohomology of  $M$  is defined as (Borel)

$$H_G^*(M) = H^*(M \times_G EG)$$

where  $EG \rightarrow BG$  is a classifying space for  $G$ -principal bundles.

- H. Cartan introduced “the equivariant de Rham differential forms”

$$(\Omega^*(M) \otimes W(\mathfrak{g}))^G$$

and equivariant exterior derivative, and showed that this gives the same cohomology up to  $\mathbb{Z}_2$ -grading when the  $G$ -action is locally free.

- Block and Getzler “globalized” the Cartan’s version and showed that its cohomology is essentially the same as periodic cyclic homology of the smooth crossed product algebra  $\mathcal{A}$ , to be defined later.

(for a compact Lie group  $G$  acting on a compact manifold  $M$ )  
 An invariant (pseudo-)differential operator

$$P : \Gamma(E) \rightarrow \Gamma(F)$$

Conclusion

\*\*\*\*\*

The noncommutative “space”:  $\mathcal{A}$   
 Elements of  $\mathcal{A}$  are in  $C^\infty(M \times G)$ ,  
 with product

$$(a * b)(x, g) = \int_G a(x, h) b(h^{-1}x, h^{-1}g) d\mu(h).$$

Let the group action be  $\rho : G \times M \rightarrow M$ .

Also use  $\rho$  for the equivariant map  $\rho : G \times E \rightarrow E$ .

The algebra  $\mathcal{A}$  acts on sections of a vector bundle  $E$  this way:

$$(\rho(a) \cdot s)(x) = \int_G a(x, g) (\rho(g)s)(g^{-1}x) dg.$$

The special case:  $\mathcal{H}$ , the (graded)  $L^2$  sections  $L^2(E) \oplus L^2(F)$ ,

\*\*\*\*\*

Generalization of parametrix:  $\exists Q : PQ - 1$  and  $QP - 1$  are smoothing when composed with any  $\rho(\phi)$ ,  $\phi \in \mathcal{A}$ .

Then it is essentially self-adjoint on  $\mathcal{H}$  (Kordyukov 1991).

If  $D^2$  has scalar symbol, then we have a regular spectral triple; there are many examples.

Spectral triple:  $(\mathcal{A}, \mathcal{H}, D)$ ,

$\mathcal{A}$  as above;  $\mathcal{H}$  as above;

Let  $D$  is a  $G$ -invariant, 1st order, symmetric, transversally elliptic operator.

Then it is essentially self-adjoint on  $\mathcal{H}$  (Kordyukov 1991).

If  $D^2$  has scalar symbol, then we have a regular spectral triple; there are many examples.

We have seen the Connes-Moscovici local index formula involves traces of operators like

$$a^0(da^1)^{(k_1)} \dots (da^n)^{(k_n)}$$

composed with powers of  $|D|^{-1}$

For our purpose, we view those operators in the first line as elements in a much bigger algebra  $\Psi(E) \rtimes G$  (See Appendix).

Wave front relation of  $A \in \Psi(E) \rtimes G$ ,

$$WF'(K_A) \in \{(\xi, g_*\xi) : \xi \in T_{G,x}^*M\};$$

compared to  $A \in \Psi(E)$ ,

$$WF'(K_A) \in \{(\xi, \xi) : \xi \in T_x^*M\}.$$

Wave front relation of  $A \in \Psi(E) \rtimes G$ ,

$$WF'(K_A) \in \{(\xi, g_*\xi) : \xi \in T_{G,x}^*M\};$$

compared to  $A \in \Psi(E)$ ,

$$WF'(K_A) \in \{(\xi, \xi) : \xi \in T_x^*M\}.$$

Using the composition and pushing rules of wave front sets.  
 here is how a typical index formula looks like:

$$Trace(\rho(f)(1 + P^*P + K_1)^{-s}) - Trace(\rho(f)(1 + PP^* + K_2)^{-s})$$

with

(A) with  $1 + P^*P + K_1, 1 + P^*P + K_2$  elliptic;

(B) and  $K_1, K_2$  are chosen so “small” as to be absorbed by  $\rho(f)$   
 to smoothing operators.

For  $A \in \Psi \rtimes G$  and  $D$  the part of the spectral triple:

Following Grubb and Seeley (1995) we have the asymptotic behavior of resolvent along a ray

$$\text{Trace}(A(D^2 - \lambda)^{-1}), |\lambda| \rightarrow \infty$$

which gives equivalent information about poles of zeta functions

$$\text{Trace}(A|D|^{-s}).$$

For  $A \in \Psi \rtimes G$  and  $D$  the part of the spectral triple:

Following Grubb and Seeley (1995) we have the asymptotic behavior of resolvent along a ray

$$\text{Trace}(A(D^2 - \lambda)^{-1}), |\lambda| \rightarrow \infty$$

which gives equivalent information about poles of zeta functions

$$\text{Trace}(A|D|^{-s}).$$

Trace formula in  $\Psi \rtimes G$  amounts to the asymptotic expansion (as  $\mu \rightarrow \infty$ ) of oscillatory integrals locally of the form:

$$\mu^{-m} \int_{\mathbb{R}^{2n}} \int_G e^{i\mu(x-gx, \xi)} q(x, g, \xi) dg d\xi dx$$

(Malgrange) Let  $\phi$  be a real valued nonzero analytic function on  $\mathbb{R}^N$ . For  $u \in C_c^\infty(\mathbb{R}^N)$  (real or complex valued) a test function, let  $I(\tau)$  be the oscillatory integral

$$I_{\phi,u}(\tau) = \int_{\mathbb{R}^N} e^{i\tau\phi(x)} u(x) d\text{vol}(x).$$

Then for  $\tau \rightarrow \infty$

$$I(\tau) = \sum_{\alpha,p,q} c_{\alpha,p,q}(u) \tau^{\alpha-p} (\ln \tau)^q,$$

where  $\alpha \leq 0$  runs through a finite set of rational numbers,  $p, q \in \mathbb{N}$  and  $0 \leq q < n$ . Moreover  $c_{\alpha,p,q}$  are all distributions with support inside

$$S_\phi = \{x \in \mathbb{R}^N : d\phi(x) = 0\},$$

and with finite orders not exceeding  $N$ .

Conclusions about  $(\mathcal{A}, \mathcal{H}, D)$ :

(1) It has dimension spectrum in  $\mathbb{Q}$ , starting from the highest transversal dimension of the *G*-CW complex.

Conclusions about  $(\mathcal{A}, \mathcal{H}, D)$ :

(1) It has dimension spectrum in  $\mathbb{Q}$ , starting from the highest transversal dimension of the *G*-CW complex.

(2) Recall the functionals defined in (CM95) (needed for local index formula)

$$\tau_k^{|D|}(A) = \text{Res}_{z=0} z^k \text{Trace}(A|D|^{-z}).$$

$\tau_k^{|D|}$  vanishes for  $k > \dim M + \dim G$ .

Conclusions about  $(\mathcal{A}, \mathcal{H}, D)$ :

(1) It has dimension spectrum in  $\mathbb{Q}$ , starting from the highest transversal dimension of the *G*-CW complex.

(2) Recall the functionals defined in (CM95) (needed for local index formula)

$$\tau_k^{|D|}(A) = \text{Res}_{z=0} z^k \text{Trace}(A|D|^{-z}).$$

$\tau_k^{|D|}$  vanishes for  $k > \dim M + \dim G$ .

(3)  $\tau_k^{|D|}$  are decided by the symbol near a conic neighborhood of  $T_G^*M$  in  $T^*M \setminus \{0\}$ .

Conclusions about  $(\mathcal{A}, \mathcal{H}, D)$ :

(1) It has dimension spectrum in  $\mathbb{Q}$ , starting from the highest transversal dimension of the *G*-CW complex.

(2) Recall the functionals defined in (CM95) (needed for local index formula)

$$\tau_k^{|D|}(A) = \text{Res}_{z=0} z^k \text{Trace}(A|D|^{-z}).$$

$\tau_k^{|D|}$  vanishes for  $k > \dim M + \dim G$ .

(3)  $\tau_k^{|D|}$  are decided by the symbol near a conic neighborhood of  $T_G^*M$  in  $T^*M \setminus \{0\}$ .

(4) Therefore, renormalization, as in CM95, is not needed.

## Appendix 1:

The algebra  $\Psi(E) \rtimes G$ : an element is a continuous function :  $G \rightarrow \Psi(E)$ , with product

$$(P * Q)(g) = \int_G P(h) \cdot [((h^{-1})_* Q)(h^{-1}g)] d\mu(h),$$

There is an action on the sections  $\Psi^k(E, E) \rtimes G$  on  $\Gamma(E)$ , defined as:

for  $P = P(g)$  in  $\Psi^\infty(E, E) \rtimes G$ ,

$$(Ps)(x) = \int_G P(g) \rho(g)(s(g^{-1}x)) d\mu(g),$$

$\Psi^\infty(E, E) \rtimes G$  is a  $\Psi^\infty(E, E)$  bimodule (but be careful of the module map)

Operators in  $\Psi^k(E, E) \rtimes G$  has order  $k$  compatible to  $\Psi^{k'}(E, E)$  (the  $\mathbb{Z}$ -grading of  $\Psi$ )

## Appendix 2:

Let  $(\mathcal{A}, \mathcal{H}, D)$  be an even spectral triple defined by a first order transversally elliptic pseudo-differential operator  $D$  and with all the above conditions.

The Connes character  $ch(\mathcal{A}, \mathcal{H}, D)$  in periodic cyclic cohomology is represented by the following even cocycle in the periodic cyclic cohomology:

$$\phi_{2m}(a_0, \dots, a_{2m}) = \sum_{k \in \mathbb{N}^{2m}, q \geq 0} c_{2m, k, q} \cdot \tau_q \left( \gamma a^0 (da_1)^{(k_1)} \dots (da_{2m})^{(k_{2m})} |D|^{-2|k| - 2m} \right) \quad (1)$$

for  $m > 0$  and

$$\phi_0(a^0) = \tau_{-1}(\gamma a^0). \quad (2)$$

## Appendix 3:

In the above formula  $k = (k_1, \dots, k_{2m}) \in \mathbb{N}^{2m}$  are multi-indices and  $c_{2m,k,q}$  are universal constants given by

$$c_{2m,k,q} = \frac{(-1)^{|k|}}{k! \tilde{k}!} \sigma_q(|k| + m), \quad (3)$$

where  $k! = k_1! \dots k_{2m}!$ ,  $\tilde{k}! = (k_1 + 1)(k_1 + k_2 + 2) \dots (k_1 + \dots + k_{2m} + 2m)$ , and for any  $N \in \mathbb{N}$ ,  $\sigma_q(N)$  is the  $q$ -th elementary polynomial of the set  $\{1, 2, \dots, N-1\}$ .
