Holomorphic dynamics Workshop

In celebration of John Milnor's 75th birthday

Fields Institute, Toronto, March 7-11, 2006

$f_0(z)$ holomorphic near 0 $f_0(0) = 0$

parabolic fixed point: $f'_0(0)$ a root of unity

1-parabolic and non-degenerate

$$f_0(z) = z + a_2 z^2 + \dots \quad a_2 \neq 0$$

near-parabolic fixed point: $f'(0) = e^{2\pi i \alpha}$, α small

irrationally indifferent

$$f(z) = e^{2\pi i \alpha} z + O(z^2) \quad \alpha \in \mathbb{R} \setminus \mathbb{Q}$$

$$\alpha = \frac{1}{a_1 \pm \frac{1}{a_2 \pm \frac{1}{a_3 \pm \dots}}} \quad \text{where } a_i \in \mathbb{N}$$

large continued fraction coefficients: $a_i \geq N$

The Goal of This Talk

Define

parabolic renormalization: $f_0 \rightsquigarrow \mathcal{R}_0 f_0$

$$\mathcal{R}_0 f_0(z) = z + O(z^2) \quad \text{1-parabolic}$$

near-parabolic renormalization: $f \rightsquigarrow \mathcal{R}f$

$$\mathcal{R}f(z) = e^{2\pi i\beta} z + O(z^2) \quad \beta = -\frac{1}{\alpha}$$

it is induced from the first return map
to a certain fundamental domain

Present the class \mathcal{F}_1 of 1-parabolic maps

it is invariant under the renormalizations

the renormalizations are contracting/hyperbolic

Plan

- Definition of Fatou coordinates and horn map
- Parabolic bifurcation/implosion and the return map (Douady-Hubbard-Lavaurs)
- Parabolic and near-parabolic Renormalizations
- Statements of Theorems
- Class \mathcal{F}_1 and its characterization
- About the proof of invariance

Fatou coordinates Φ_{attr} , Φ_{rep} and Horn map E_{f_0}

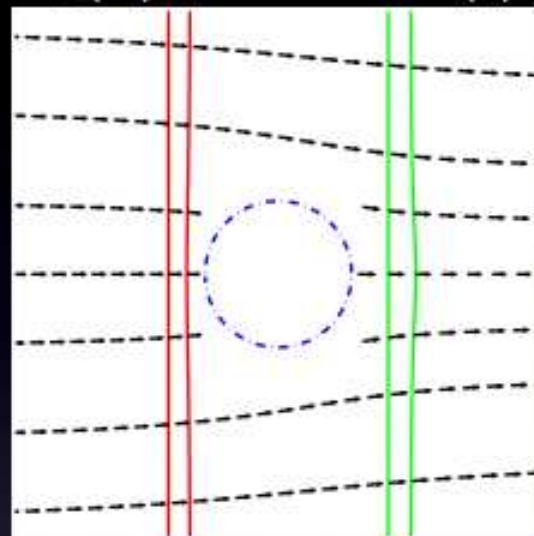

$$f_0(z) = z + a_2 z^2 + \dots$$

near 0

$$F_0(w) = w + 1 + o(1)$$

near ∞

$$w = -\frac{c}{z}$$

$$E_{f_0}(z) = \Phi_{attr} \circ \Phi_{rep}^{-1}$$

Φ_{rep}

Φ_{attr}

$$T(w) = w + 1$$

$$T(w) = w + 1$$

$$\Phi_{\dots}(f_0(z)) = \Phi_{\dots}(z) + 1$$

Perturbation

$$f'(0) = e^{2\pi i \alpha}, \quad \alpha \text{ small} \quad |\arg \alpha| < \frac{\pi}{4}$$

E_f depends continuously on f
(after a suitable normalization)

$$\chi_f(z) = z - \frac{1}{\alpha}$$

Parabolic Bifurcation/Implosion

When a parabolic point is perturbed....

Discontinuous change
of Julia sets

New complicated
dynamics is created
by the orbits going
through the “gate”

New dynamics can be
understood via the
return map

Parabolic Renormalization

Normalize the Fatou coordinates so that

$$E_{f_0}(z) = z + o(1) \quad (\text{Im } z \rightarrow +\infty)$$

Let $\Pi(z) = e^{2\pi iz}$ then

$$\Pi : \mathbb{C}/\mathbb{Z} \xrightarrow{\cong} \mathbb{C}^*$$

Parabolic Renormalization

$$\mathcal{R}_0 f_0 = \Pi \circ E_{f_0} \circ \Pi^{-1}$$

0 is 1-parabolic fixed point

Near-parabolic Renormalization (cylinder renorm.)

$$\begin{aligned}\mathcal{R}f &= \Pi \circ \tilde{\mathcal{R}}f \circ \Pi^{-1} \\ &= \Pi \circ \chi_f \circ E_f \circ \Pi^{-1} \\ &= e^{2\pi i\beta} z + O(z^2)\end{aligned}$$

where $\beta = -\frac{1}{\alpha} \pmod{\mathbb{Z}}$

or $\alpha = \frac{1}{m - \beta} \pmod{\mathbb{Z}}$ ($m \in \mathbb{N}$)

Renormalization: The Picture

$$f(z) = e^{2\pi i \alpha} z + O(z^2) = e^{2\pi i \alpha} f_0(z) \text{ where } f_0(z) = z + O(z^2) \text{ 1-parabolic}$$
$$f \leftrightarrow (\alpha, f_0)$$

Write $\mathcal{R}f(z) = e^{-2\pi i \frac{1}{\alpha}} \mathcal{R}_\alpha f_0(z)$ then $\mathcal{R} : (\alpha, f_0) \mapsto (-\frac{1}{\alpha}, \mathcal{R}_\alpha f_0)$

\mathcal{R} hyperbolic?
 $(\mathcal{R}_\alpha \text{ contracting?})$
 $\mathcal{R}_\alpha f_0 \rightarrow \mathcal{R}_0 f_0 \ (\alpha \rightarrow 0)$
 \mathcal{R}_0 contracting?
YES for α small

Main Theorems

Theorem 1 *Let $P(z) = z(1+z)^2$. There exist bounded simply connected open sets V and V' with $0 \in V \subset \bar{V} \subset V' \subset \mathbb{C}$ such that the class*

$$\mathcal{F}_1 = \left\{ f = P \circ \varphi^{-1} : \varphi(V) \rightarrow \mathbb{C} \left| \begin{array}{l} \varphi : V \rightarrow \mathbb{C} \text{ is univalent} \\ \varphi(0) = 0, \varphi'(0) = 1 \end{array} \right. \right\}$$

satisfies the following:

univalent = holomorphic and injective

(0) *every $f \in \mathcal{F}_1$ is non-degenerate;*

(i) *$\mathcal{F}_0 \setminus \{\text{quadratic polynomial}\}$ can be naturally embedded into \mathcal{F}_1 (in particular, $\mathcal{R}_0^n(z + z^2) \in \mathcal{F}_1$ $n = 1, 2, \dots$);*

(ii) *The renormalization \mathcal{R}_0 is well defined on \mathcal{F}_1 so that $\mathcal{R}_0(\mathcal{F}_1) \subset \mathcal{F}_1$;*

(iii) *If we write $\mathcal{R}_0 f = P \circ \psi^{-1}$, then ψ can be extended univalently to V' ;*

(iv) *$f \mapsto \mathcal{R}_0 f$ is “holomorphic.”*

Theorem 2 *The above statements hold for \mathcal{R}_α for α small. Hence there exists an N such that the above holds for*

$$\alpha = \frac{1}{m + \beta} \quad \text{with } m \in \mathbb{N}, \beta \in \mathbb{C} \text{ and } |\beta| \leq 1.$$

$$P(z) = z(1+z)^2 \text{ and } V, V'$$

$$P(0) = 0, \quad P'(0) = 1$$

$$\text{critical points: } -\frac{1}{3} \text{ and } -1 \quad \text{critical values: } P(-\frac{1}{3}) = -\frac{4}{27} \text{ and } P(-1) = 0$$

$$\eta = 2$$

V'

\xrightarrow{P}

$$\frac{4}{27}e^{-2\pi\eta}$$

$$\frac{4}{27}e^{2\pi\eta}$$

V slightly smaller domain than V'

$$\mathcal{F}_0 = \left\{ f : U_f \rightarrow \mathbb{C} \left| \begin{array}{l} 0 \in U_f \text{ open and connected } \subset \mathbb{C}, \\ f \text{ is holomorphic in } U_f, \ f(0) = 0, \ f'(0) = 1, \\ f : U_f \setminus \{0\} \rightarrow \mathbb{C}^* \text{ is a branched covering map} \\ \text{with a unique critical value,} \\ \text{all critical points are of local degree 2} \end{array} \right. \right\}$$

$$\mathcal{R}_0(\mathcal{F}_0) \subset \mathcal{F}_0$$

$$z + z^2, \mathcal{R}_0(z + z^2), \dots \in \mathcal{F}_0$$

This class was used in the proof of HD=2 for generic Julia sets on the boundary of the Mandelbrot set, and for the the boundary of the Mandelbrot set itself.

Also compare with the works on critical circle maps
(for example, Epstein-Yampolsky)

Contraction and Hyperbolicity

Theorem 3 *Modifying the definition slightly (requiring that φ has a quasi-conformal extension to \mathbb{C}), \mathcal{F}_1 is in one to one correspondence with the Teichmüller space $\text{Teich}(W)$ of $W = \mathbb{C} \setminus \bar{V} (\simeq \mathbb{D}^*)$. The induced map $\mathcal{R}_0^{\text{Teich}}$ is a uniform contraction with respect to the Teichmüller distance. (The Lipschitz constant $\leq \exp(-2\pi \text{mod}(V' \setminus \bar{V}))$.)*

Theorem 4 *The above statements hold for the fiber map \mathcal{R}_α for α small. Hence the total renormalization \mathcal{R} is hyperbolic in this region.*

$$\mathcal{F}_1 \ni f = P \circ \varphi^{-1} \rightsquigarrow [\tilde{\varphi}|_W] \in \text{Teich}(W) = \{\psi : W \rightarrow \mathbb{C} \text{ qc}\} / \sim$$

where $\tilde{\varphi}$ is a quasiconformal extension of φ to \mathbb{C} .

Royden-Gardiner Theorem (Teichmüller distance = Kobayashi distance)
cotangent space = {integrable holomorphic quadratic differentials}
modulus-area inequality for holom. quad. differentials
isoperimetric inequality for holom. quad. differentials
modified Carleman's inequality

Theorem 2 follows from Theorem 1 and the continuity of E_f with respect to f .

We outline the proof of Theorem 1.

one cannot compute $\mathcal{R}_0 f$!

In order to define an invariant class of maps, we need a way to recognize that $\mathcal{R}_0 f$ belongs to this class.

We characterize our class by covering property (as incomplete/partial ramified covering over \mathbb{C})

The Class \mathcal{F}_1 -- starting point and goal

We characterize our class by covering property
(as incomplete/partial ramified covering over \mathbb{C})

“ f and g have the same covering properties” or
 $Dom(f)$ and $Dom(g)$ are the same when viewed as, in classical terms,
Riemann surfaces spread cover \mathbb{C}

$$\begin{array}{ccccc} \mathbb{C} \hookleftarrow & Dom(f) & \xrightarrow[\cong]{\varphi} & Dom(g) & \hookrightarrow \mathbb{C} \\ & \downarrow f & & \downarrow g & \\ & \mathbb{C} & \xrightarrow[\text{identity}]{=} & \mathbb{C} & \\ & & \text{(or a canonical isomorphism)} & & \end{array}$$

0 = the fixed point
 ∞ = designated omitted point
the critical value

$$g = f \circ \varphi^{-1}$$

We will characterize $f \in \mathcal{F}_1$ by color-tiling the domains (V replaced by V')

exercise: $\check{Q}(z) = \frac{z(1+z)^4}{(1-z)^6} \in \mathcal{F}'_1$ after rescaling (V is replaced by V' for \mathcal{F}'_1)

Before the proof...

send the parabolic fixed point to ∞

dynamics is already close to a translation

Fatou coordinates will be “close” to the identity or affine transformation

we must handle $f = P \circ \varphi^{-1}$ with arbitrary univalent function φ

it is easier to work with univalent functions in $\mathbb{C} \setminus \overline{\mathbb{D}}$

(Area theorem etc)

open the slit $(-\infty, -1]$ to the unit disk and obtain $Q(z) = z \frac{(1 + \frac{1}{z})^6}{(1 - \frac{1}{z})^4}$

with the same covering property

$$Q = \psi_0^{-1} \circ P \circ \psi_1 \text{ where } \psi_0(z) = -\frac{4}{z}, \psi_1(z) = -\frac{4z}{(1+z)^2} = 4f_{Koebe}\left(-\frac{1}{z}\right)$$

We will work with $f \in \mathcal{F}_1^Q$ instead of \mathcal{F}_1

$$\mathcal{F}_1^Q = \left\{ f = Q \circ \varphi^{-1} : \varphi(V) \rightarrow \hat{\mathbb{C}} \left| \begin{array}{l} \varphi : \hat{\mathbb{C}} \setminus E \rightarrow \hat{\mathbb{C}} \text{ is univalent} \\ \varphi(\infty) = \infty, \lim_{z \rightarrow \infty} \frac{\varphi(z)}{z} = 1 \\ \text{and } 0 \notin \text{Image}(\varphi) \end{array} \right. \right\}$$

$$E = \left\{ x + iy \in \mathbb{C} : \left(\frac{x + 0.18}{1.24} \right)^2 + \left(\frac{y}{1.04} \right)^2 \leq 1 \right\} \quad V = \psi_1(\hat{\mathbb{C}} \setminus E)$$

How to see that $\mathcal{R}_0 f$ is in \mathcal{F}'_1

$\mathcal{R}_0 f$ was defined via Horn map E_f and $\Pi(z) = e^{2\pi i z}$

$$\mathcal{R}_0 f = \Pi \circ E_f \circ \Pi^{-1}$$

For E_f , domain = repelling Fatou coordinate

range = attracting Fatou coordinate

Make a color-tiling according to the range (= attracting Fatou coordinate) and compare with that of P

“checkerboard picture”

Π

Compare $\mathcal{R}_0 f$ with P or its log lift

repelling
side

$P \downarrow E_f$

\downarrow log lift of P

attracting
side

Compare $\mathcal{R}_0 f$ with log lift of Q

E_f

log lift of Q

This is the starting point of the proof

Danger: inverse orbits may fall off from the domain of definition

More details: Checkerboard picture for Q

What we need to do

Left

guarantee that certain
inverse images arrive
in the domain of
repelling Fatou
coordinate

construct a Riemann
surface X on which
an appropriate inverse
branch of f can be
lifted

Middle

take multiple inverse
images of D_1
($D_0, D'_0, D_{-1}, D''_{-1}$)
and bound their location
they are glued together
like the tiles for P

Right

distortion estimates
for attracting Fatou
coordinate
bound the location
and shape of D_1

determine the domain
where the attracting
Fatou coord. is
univalent and apply
Golusin inequality

many inequalities (~30)
needed to be checked
with help of computers

**Happy Birthday
Jack!**
