

# Another Look at Provable Security

Alfred Menezes

(joint work with Neal Koblitz)

# The need for provable security

- ▶ Since the mid 1970's, cryptographic protocols for achieving various goals have been proposed at a furious rate.
- ▶ It is very desirable to obtain mathematically rigorous proofs that protocols meet their **goals** under some plausible **assumptions**.
  - If nothing else, the desire for rigour encourages researchers to carefully define their security notions and precisely state their assumptions.
- ▶ Security proofs generally take the form of a **reduction**:
  - Argue that if the protocol can be broken, then a (reasonable) mathematical assumption is invalid.

However, it is not always clear what these proofs *really* mean in practice.

# RSA key generation

Alice does the following:

1. Select primes  $p$  and  $q$  of the same bitlength.
2. Compute  $n = pq$  and  $\phi = (p - 1)(q - 1)$ .
3. Select arbitrary  $e$ ,  $1 < e < \phi$ , with  $\gcd(e, \phi) = 1$ .
4. Compute  $d = e^{-1} \bmod \phi$ .

Alice's **public key** is  $(n, e)$ ; her **private key** is  $d$ .

Computing  $d$  from  $(n, e)$  is equivalent to factoring  $n$ .

# Full-Domain-Hash RSA signature scheme

**Signature generation:** To sign  $m \in \{0, 1\}^*$ , Alice does:

1. Compute  $h = H(m)$ , where  $H : \{0, 1\}^* \rightarrow [0, n - 1]$  is a (public) hash function.
2. Compute  $s = h^d \bmod n$ .

Alice's signature on  $m$  is  $s$ .

**Signature verification:** To verify, Bob does:

1. Obtain Alice's public key  $(n, e)$ .
2. Compute  $h = H(m)$  and verify that  $h = s^e \bmod n$ .

# Full-Domain-Hash RSA signature scheme

**Signature generation:** To sign  $m \in \{0, 1\}^*$ , Alice does:

1. Compute  $h = H(m)$ , where  $H : \{0, 1\}^* \rightarrow [0, n - 1]$  is a (public) hash function.
2. Compute  $s = h^d \bmod n$ .

Alice's signature on  $m$  is  $s$ .

**Signature verification:** To verify, Bob does:

1. Obtain Alice's public key  $(n, e)$ .
2. Compute  $h = H(m)$  and verify that  $h = s^e \bmod n$ .

**Question:** Is RSA-FDH secure?

# Security definition

**Definition:** (Goldwasser, Micali & Rivest; 1984)

A signature scheme is **secure** if a computationally bounded attacker who has access to a signing oracle is unable (with non-negligible probability) to obtain a valid signature for any message that it did not previously present to the oracle.

# Necessary conditions for security of RSA-FDH

1. The **RSA problem** should be intractable:

Given  $n, e, h$ , find  $s$  such that  $h = s^e \bmod n$ .

► Clearly  $\text{RSA} \leq_P \text{FACTOR-}n$ .

► **Open Question:**  $\text{FACTOR-}n \leq_P \text{RSA}$ ?

►  $e = 3$  is commonly used in practice.

► Boneh and Venkatesan (1998) proved that, if  $\text{FACTOR-}n \leq_P \text{RSA-3}$  where the reduction algorithm uses only algebraic operations, then  $\text{FACTOR-}n$  is in  $P$ .

► Nevertheless, we assume that  $\text{RSA-3}$  and  $\text{RSA}$  are as hard as  $\text{FACTOR-}n$  in practice.

# Necessary conditions for security of RSA-FDH

2.  $H$  should be **preimage resistant**:

- Otherwise, an attacker could first select  $s$ , then compute  $h = s^e \bmod n$ , and finally select  $m$  with  $H(m) = h$ .

# Necessary conditions for security of RSA-FDH

2.  $H$  should be **preimage resistant**:

- ▶ Otherwise, an attacker could first select  $s$ , then compute  $h = s^e \bmod n$ , and finally select  $m$  with  $H(m) = h$ .

3.  $H$  should be **collision resistant**:

- ▶ Otherwise, an attacker could find  $m_1, m_2$  with  $H(m_1) = H(m_2)$  and induce Alice to sign  $m_1$ , thereby obtaining Alice's signature on  $m_2$ .

# Necessary conditions for security of RSA-FDH

2.  $H$  should be **preimage resistant**:

- ▶ Otherwise, an attacker could first select  $s$ , then compute  $h = s^e \bmod n$ , and finally select  $m$  with  $H(m) = h$ .

3.  $H$  should be **collision resistant**:

- ▶ Otherwise, an attacker could find  $m_1, m_2$  with  $H(m_1) = H(m_2)$  and induce Alice to sign  $m_1$ , thereby obtaining Alice's signature on  $m_2$ .

**Question:** Are these conditions sufficient?

# Random oracle model

- ▶ The hash function  $H$  is modeled as a (public) random function.
- ▶ The adversary's probability of success is assessed over all possible hash functions.
- ▶ This is the random oracle assumption.

# Security proof

**Theorem** (Bellare & Rogaway; 1993) RSA-FDH is a secure signature scheme in the random oracle model under the assumption that the RSA problem is intractable.

**Proof:**

1. Let  $F$  be an attacker that breaks RSA-FDH.  $F$  can make calls to two subroutines, a hash oracle  $H$  and a signing oracle  $S$ . At the end of its operation,  $F$  produces (with non-negligible probability) a signature for a message not presented to the signing oracle. We show how such a program  $F$  can be used to solve the RSA problem.

2. Suppose that we are given an instance  $(n, e, y)$  of the RSA problem. Our task is to find  $x$  such that  $y \equiv x^e \pmod{n}$ .
3. We make two assumptions about  $F$ 's operation:
  - a) Before querying  $S$  with  $m$ ,  $F$  always queries  $H$  with  $m$ .
  - b)  $F$  makes (at most)  $q$  (distinct)  $H$ -queries,  $m_1, m_2, \dots, m_q$ .
  - c)  $F$  outputs a valid signature on one of the  $m_i$ 's.
4. We select a random index  $j \in [1, q]$ .
5. We run  $F$  with input  $(n, e)$  and wait for its queries.

6. For all  $H$ -queries except for the  $j$ th one, we select a random  $x_i \in [0, n - 1]$  and respond with  $H(m_i) = x_i^e \bmod n$ .  
For the  $j$ th  $H$ -query, we respond with  $H(m_j) = y$ .
7. If an  $S$ -query on  $m_i$  is issued (where  $i \neq j$ ) we respond with  $x_i$ .  
(Note: this is a valid signature.)  
If an  $S$ -query on  $m_j$  is issued, we give up (restart  $F$  and select a new  $j$ ).

8. Suppose that  $F$  outputs a valid signature  $s$  on  $m_j$ . Then  $s^e \equiv H(m_j) \equiv y \pmod{n}$ , and so  $x = s$  is the solution to our RSA problem instance.  
If  $F$  does not output a valid signature on  $m_j$ , we restart  $F$  (and select a new  $j$ ).
9. If we repeat this procedure  $k$  times, the probability that every single time we fail is at most  $(1 - 1/q)^k$ .  $\square$

# Tightness of the reduction

- ▶ The forgery program  $F$  would have to be used roughly  $q$  times in order to find the desired  $e$ -th root of  $y$ .
  - This is a highly **non-tight** reduction.
- ▶ Suppose that  $n$  is a 1024-bit integer.
- ▶ The NFS takes about  $2^{80}$  steps to factor  $n$ .
  - Suppose that the RSA problem cannot be solved in fewer than  $2^{80}$  steps.
- ▶ Suppose the forger can make at most  $q = 2^{70} H$  queries.
- ▶ Then the Bellare-Rogaway proof says that a successful forger must require time at least  $2^{10}$ .
- ▶ So, if we desire the assurance that any forger must take time at least  $2^{80}$  then we need to select  $n$  so that factoring takes time at least  $2^{150}$  steps.
  - That is, we should use a  $\approx 4000$ -bit modulus  $n$ .

# A tighter reduction

- In 2000, Coron gave a different reduction which lowered the number to  $F$ -invocations to  $q_s$  (where  $q_s$  is a bound on the number of signature queries).

- Coron (2001) proved that no “tighter” reduction is possible.

# Practical interpretation

- ▶ Suppose that  $n$  is a 1024-bit integer.
- ▶ Suppose that the forger can make at most  $q_s = 2^{20}$  signature queries.
- ▶ Then Coron's proof says that a successful forger must require time at least  $2^{60}$ .
- ▶ So, if we desire the assurance that any forger must take time at least  $2^{80}$  then we need to select  $n$  so that factoring takes time at least  $2^{100}$  steps.
  - That is, we should use a 1500-bit modulus  $n$ .

# RSA-PSS (simplified)

(Bellare & Rogaway, 1996)

**Signature generation:** To sign  $m \in \{0, 1\}^*$ , Alice does:

1. Select a random bit string  $r$ .
2. Compute  $h = H(m, r)$ , where  $H : \{0, 1\}^* \rightarrow [0, n - 1]$  is a (public) hash function.
3. Compute  $s = h^d \bmod n$ .

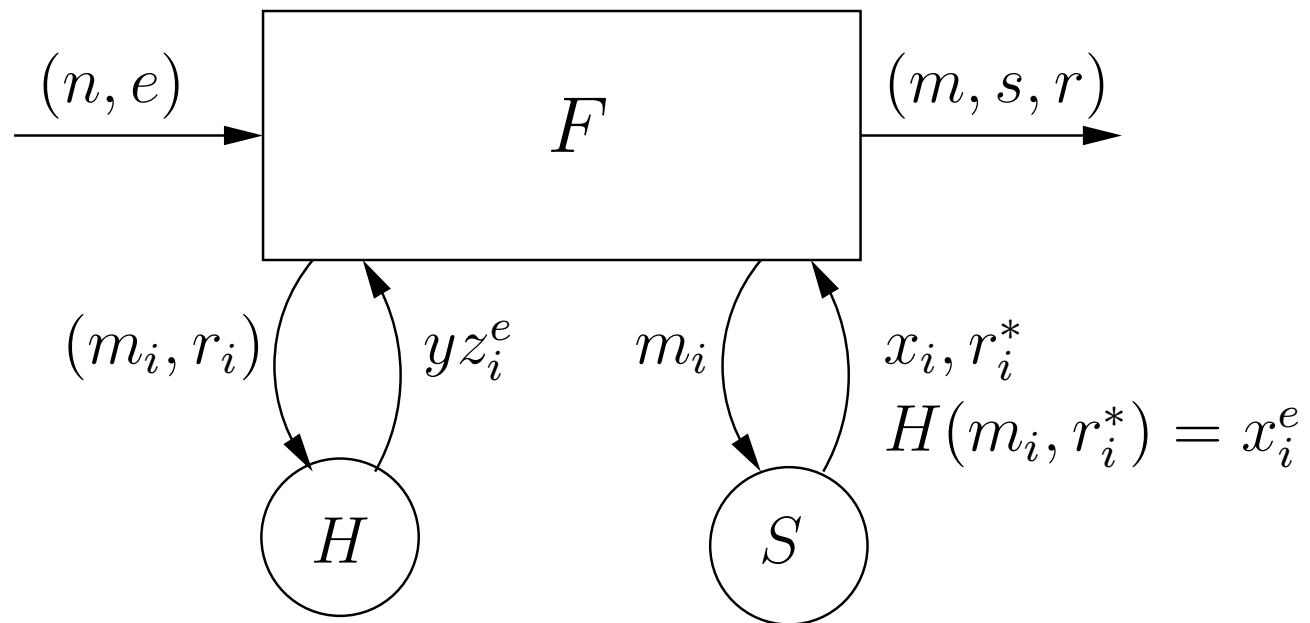

Alice's signature on  $m$  is  $(s, r)$ .

**Signature verification:** To verify, Bob does:

1. Obtain Alice's public key  $(n, e)$ .
2. Compute  $h = H(m, r)$  and verify that  $h = s^e \bmod n$ .

# Security proof

The security of RSA-PSS can be **tightly** related to the hardness of the RSA problem.

# FDH versus PSS

- ▶ Both RSA-FDH and RSA-PSS have security proofs under the same assumptions.
- ▶ The signing and verification procedures are equally fast.
- ▶ Advantage of RSA-FDH: No random numbers are needed.
- ▶ Advantage of RSA-PSS: Has a **tight** reduction.

Standards have been favouring RSA-PSS.

# FDH or PSS?

- ▶ The security of RSA-FDH is tightly related to the hardness of the following problem:
  - **RSA1**: Given  $(n, e)$ , and a set of  $q$  values  $y_i$  randomly chosen from  $[0, n - 1]$ , you are permitted at any time to select up to  $q_s$  of those  $y_i$  for which you will be given solutions  $x_i$  to  $x_i^e \equiv y_i \pmod{n}$ . You must produce a solution  $x_i^e \equiv y_i \pmod{n}$  for one of the remaining  $y_i$ .
- ▶ Even though there is no tight reduction from RSA to RSA1, it is reasonable to conjecture that RSA and RSA1 are equivalent in practice — no one will ever be able to find a solution to RSA1 without being able to solve RSA in essentially the same amount of time.
- ▶ One reasonable conclusion: The lack of a tight security reduction for RSA-FDH is not a concern.

# RSA-KW (Katz-Wang, 2003)

**Key generation:** Alice selects a (secret) random bit string  $R$ .

**Signature generation:** To sign  $m \in \{0, 1\}^*$ , Alice does:

1. Compute the **bit**  $b = H_2(m, R)$ .
2. Compute  $h = H(m, b)$ .
3. Compute  $s = h^d \bmod n$ .

Alice's signature on  $m$  is  $(s, b)$ .

**Signature verification:** To verify, Bob does:

1. Obtain Alice's public key  $(n, e)$ .
2. Compute  $h = H(m, b)$  and verify that  $h = s^e \bmod n$ .

# Security proof

The security of RSA-KW can be **tightly** related to the hardness of the RSA problem.

# FDH or KW?

- ▶ The security of RSA-KW is also tightly related to the hardness of the following problem:  
**RSA2**: Given  $(n, e)$ , and a set of  $q$  pairs of values  $(y_i, z_i)$  chosen at random from  $[0, n - 1]$ , you are permitted at any time to select up to  $q_s$  of those pairs for which you will be given the  $e$ -th root modulo  $n$  of exactly one (randomly selected) element of the pair. You must produce an  $e$ -th root of either element in one of the remaining pairs.
- ▶ Coron's result implies that there is no tight reduction from the RSA2 problem to the RSA1 problem.
- ▶ However, it seems very unlikely that RSA1 would be easier to solve in practice than RSA2.

# Random oracle assumption

- ▶ In practice,  $H$  is **not** a random function, so the security proof is no longer valid.
- ▶ Nevertheless, the security proof does guarantee security against attackers who do not exploit any property whatsoever of the hash function  $H$ .
- ▶ Several researchers have designed protocols that are provably secure in the random oracle model, but provably insecure whenever the random oracle is replaced by a real hash function.
- ▶ However, these protocols are very contrived and arguably support the random oracle model.

# Canetti-Goldreich-Halevi example

- ▶ Suppose signature scheme  $S$  is secure in the random oracle model (with random function  $H$ ).
- ▶ Make the following modification to  $S$  to obtain a scheme  $S'$  that is also secure in the random oracle model:
  - If  $H(m) = \text{SHA-1}(0)$  then include the private key in the signature for  $m$ .
- ▶ However,  $S'$  is clearly insecure if SHA-1 is used as the hash function.

# Canetti-Goldreich-Halevi example

- ▶ Suppose signature scheme  $S$  is secure in the random oracle model (with random function  $H$ ).
- ▶ Make the following modification to  $S$  to obtain a scheme  $S'$  that is also secure in the random oracle model:
  - If  $H(m) = \text{SHA-1}(0)$  then include the private key in the signature for  $m$ .
- ▶ However,  $S'$  is clearly insecure if SHA-1 is used as the hash function.
- ▶ The example is extended so that  $S'$  is insecure no matter what real-world hash function is used.

# General issues with provable security

- ▶ Are the definitions the ‘right’ ones?
  - Signatures, public-key encryption, key establishment, etc.
  - No resistance to side-channel attacks.

# General issues with provable security

- ▶ Are the definitions the ‘right’ ones?
  - Signatures, public-key encryption, key establishment, etc.
  - No resistance to side-channel attacks.
- ▶ Are the proofs correct?
  - The security reductions are intricate and lengthy.
  - Halevi (2005): “...as a community, we generate more proofs than we carefully verify...”
  - Halevi (2005): “...I do not expect anyone in his right mind to even read the proof, let alone carefully verify it.”

# General issues with provable security

- ▶ Are the definitions the ‘right’ ones?
  - Signatures, public-key encryption, key establishment, etc.
  - No resistance to side-channel attacks.
- ▶ Are the proofs correct?
  - The security reductions are intricate and lengthy.
  - Halevi (2005): “...as a community, we generate more proofs than we carefully verify...”
  - Halevi (2005): “...I do not expect anyone in his right mind to even read the proof, let alone carefully verify it.”
- ▶ What do the proofs really mean?
  - **Open problem:** Devise a public-key protocol  $P$  so that (i) a computational problem  $X$  has an optimal but non-tight reduction to the problem of breaking  $P$ ; (ii) if the parameters for  $P$  are selected so that breaking the related problem  $X$  is intractable, then  $P$  can be broken.

# Some questions to ponder

Let  $A$ ,  $B$  be two cryptographic protocols for the same task.

# Some questions to ponder

Let  $A$ ,  $B$  be two cryptographic protocols for the same task.

1. If  $A$  has a security proof and  $B$  doesn't, is  $A$  necessarily better than  $B$ ?
  - Example: DSA versus Schnorr.

# Some questions to ponder

Let  $A$ ,  $B$  be two cryptographic protocols for the same task.

1. If  $A$  has a security proof and  $B$  doesn't, is  $A$  necessarily better than  $B$ ?
  - ▶ Example: DSA versus Schnorr.
2. If both  $A$  and  $B$  have security proofs, which is better?
  - ▶ Depends on the assumptions (e.g. Rabin versus RSA)

# Some questions to ponder

Let  $A$ ,  $B$  be two cryptographic protocols for the same task.

1. If  $A$  has a security proof and  $B$  doesn't, is  $A$  necessarily better than  $B$ ?
  - ▶ Example: DSA versus Schnorr.
2. If both  $A$  and  $B$  have security proofs, which is better?
  - ▶ Depends on the assumptions (e.g. Rabin versus RSA)
3. If  $A$ ,  $B$  have security proofs under the same assumptions but the reduction for  $A$  is tighter, which is better?
  - ▶ Example: RSA signatures (FDH vs PSS vs KW).

# Some questions to ponder

4. If the reduction for  $A$  is highly non-tight, should we have any confidence in the security of  $A$ ?
  - ▶ Example: Schnorr signatures.

# Some questions to ponder

4. If the reduction for  $A$  is highly non-tight, should we have any confidence in the security of  $A$ ?
  - ▶ Example: Schnorr signatures.
5. If  $A$  has a security proof in the random oracle model, but  $B$  has a proof in a standard model (but with a non-standard computational assumption), which is better?
  - ▶ Example: Identity-based encryption.

# Some questions to ponder

4. If the reduction for  $A$  is highly non-tight, should we have any confidence in the security of  $A$ ?
  - ▶ Example: Schnorr signatures.
5. If  $A$  has a security proof in the random oracle model, but  $B$  has a proof in a standard model (but with a non-standard computational assumption), which is better?
  - ▶ Example: Identity-based encryption.
6. If  $A$  has a tight security proof under standard assumptions, but is twice as slow as competing protocols, should we use  $A$ ?
  - ▶ Example: Cramer-Shoup encryption.

# Summary

- ▶ Reductionist security arguments are an important tool in the design and analysis of cryptographic protocols.
- ▶ More work needs to be done to understand what these reductions really mean.
- ▶ Too early to abandon good old-fashioned cryptanalysis and prudent security engineering practices.
- ▶ Provable security: Still as much an art as a science.
