Background Motivation Questions Questions Our challenge

Background

 Target-date mutual funds are relatively new instruments (10 years in US, less in Canada)

<ロ> (四) (四) (三) (三) (三) (三)

Background Motivation Questions Questions Our challenge

Background

- Target-date mutual funds are relatively new instruments (10 years in US, less in Canada)
- TDF is an extension of fund-of-funds i.e. it is a combination of several mutual funds with specific targets of investment in stocks and bonds (40% bonds, 60% stocks)

イロン イヨン イヨン イヨン

Background Motivation Questions Questions Our challenge

Background

- Target-date mutual funds are relatively new instruments (10 years in US, less in Canada)
- TDF is an extension of fund-of-funds i.e. it is a combination of several mutual funds with specific targets of investment in stocks and bonds (40% bonds, 60% stocks)
- ▶ The equity weight is continuously adjusted in time (80% 90% when you have 40 years before retirement to 40% 50% at retirement).

イロン イヨン イヨン イヨン

Background Motivation Questions Questions Our challenge

Motivation

There is no consensus in the industry on how to roll down the equity weight until retirement (e.i. how to select the optimal glide path)

Glide Path Comparison for US Target Date Funds

Background Motivation Questions Our challenge

In relation to target-date funds one can formulate several questions.

How to rank the ability of FMs to pick better stocks?

-2

Background Motivation Questions Questions Our challenge

In relation to target-date funds one can formulate several questions.

- How to rank the ability of FMs to pick better stocks?
- Are these FMs who actively manage the funds actively manage the funds actually adding value to the overall return? (i.e. adding value by tweaking the glide path around the target value)

イロン イヨン イヨン イヨン

Background Motivation Questions Our challenge

In relation to target-date funds one can formulate several questions.

- How to rank the ability of FMs to pick better stocks?
- Are these FMs who actively manage the funds actively manage the funds actually adding value to the overall return? (i.e. adding value by tweaking the glide path around the target value)
- What is the optimal design of the glide path?

イロト イヨト イヨト イヨト

Background Motivation Questions Questions Our challenge

Questions

- The first two questions correspond more to the paradigm of portfolio management and there are many tools out there for answering these questions
- The last one can be more relevant in defining fund's characteristics and for promotion. It is related to the following situations:
 - How a given glide path matches the needs of a particular firm's employees
 - Use unique labor income distribution among employees
 - Use particular employees risk preferences
 - By this approach managers can run comparisons and present them to pension directors for promotion of their instruments.

イロン イヨン イヨン イヨン

Background Motivation Questions Questions Our challenge

 For specific preferences, there is no clear way on how to choose among target-date funds

<ロ> (四) (四) (三) (三) (三) (三)

Background Motivation Questions Questions Our challenge

- For specific preferences, there is no clear way on how to choose among target-date funds
- We want to find a useful model for comparison of strategies among different target-date funds and be able to come up with a ranking system

・ロト ・回ト ・ヨト ・ヨト

Outline our approach

Outline of the solution

 Consider uncertainty in the stock markets and labor income as stochastic processes

・ロン ・四 ・ ・ ヨン ・ ヨン

-21

7/23

Outline our approach

Outline of the solution

- Consider uncertainty in the stock markets and labor income as stochastic processes
- We consider investment in one risky asset (stock index) and in a risk-free instrument (bond)

・ロト ・回ト ・ヨト ・ヨト

Outline our approach

Outline of the solution

- Consider uncertainty in the stock markets and labor income as stochastic processes
- We consider investment in one risky asset (stock index) and in a risk-free instrument (bond)
- Given the stochastic nature of the risky asset and the labor income, the total wealth of investment in the financial markets will also behave stochastically

イロン イヨン イヨン イヨン

Outline our approach

Outline of the solution

- Consider uncertainty in the stock markets and labor income as stochastic processes
- We consider investment in one risky asset (stock index) and in a risk-free instrument (bond)
- Given the stochastic nature of the risky asset and the labor income, the total wealth of investment in the financial markets will also behave stochastically
- Formulate the problem as a stochastic control problem: to find the "optimal strategy" that maximizes the expected utility of terminal wealth at retirement

イロン イヨン イヨン イヨン

Outline our approach

Outline of the solution

- Consider uncertainty in the stock markets and labor income as stochastic processes
- We consider investment in one risky asset (stock index) and in a risk-free instrument (bond)
- Given the stochastic nature of the risky asset and the labor income, the total wealth of investment in the financial markets will also behave stochastically
- Formulate the problem as a stochastic control problem: to find the "optimal strategy" that maximizes the expected utility of terminal wealth at retirement
- We considered two different utility functions (CRRA, HARA) to capture different preferences

First model Second model Other models

Wealth

If ω_t is the fraction of wealth invested in the risky asset S_t, and labor earnings flows into the retirement account at a rate e_tdt then, the wealth process evolves according to

$$dX_t = e_t dt + X_t r dt + X_t \omega_t (\mu - r) dt + X_t \omega_t \sigma dZ_t$$

イロン イヨン イヨン イヨン

$$dX_t = e_t dt + X_t r dt + X_t \omega_t (\mu - r) dt + X_t \omega_t \sigma dZ_t$$

 We represent consumer's preferences by a constant relative risk aversion utility function (CRRA) of terminal wealth

$$U(X_T) = \frac{X_T^{1-\gamma}}{1-\gamma},$$

where γ is the parameter of relative risk aversion

イロン イヨン イヨン イヨン

First model Second model Other models

Related stochastic control problem

 \blacktriangleright We want to find the optimal strategy ω_t^* that maximizes utility from terminal wealth

$$v(t, x, e) = \max_{\omega_t} \mathbb{E}\left[rac{X_T^{1-\gamma}}{1-\gamma} | X_0 = x, e_o = e
ight]$$

イロン イ部ン イヨン イヨン 三連

First model Second model Other models

Related stochastic control problem

 \blacktriangleright We want to find the optimal strategy ω_t^* that maximizes utility from terminal wealth

$$v(t, x, e) = \max_{\omega_t} \mathbb{E}\left[\frac{X_T^{1-\gamma}}{1-\gamma}|X_0 = x, e_o = e\right]$$

 Exploiting the similarity solutions properties to reduce the order of the problem

$$Y_t = \frac{X_t}{e_t}$$

and

$$v(t,x,e)=e^{1-\gamma}u(t,y)$$

イロン イ部ン イヨン イヨン 三連

First model Second model Other models

Solution to the first problem

In this case, one gets an analytic solution

$$u(t,y) = \frac{(y+\alpha(t))^{1-\gamma}}{1-\gamma}\beta(t),$$

with

$$\begin{aligned} \alpha(t) &= \frac{1}{a_1} \left(1 - \exp\{-a_1(T-t)\} \right), \\ \beta(t) &= \exp\left\{ \left(a_o + a_1(1-\gamma) + a_2\left(\frac{1-\gamma}{\gamma}\right) \right) (T-t) \right\} \end{aligned}$$

where a_0 , a_1 and a_2 are constants depending on the parameters.

イロン イヨン イヨン イヨン

First model Second model Other models

Analytic solution

First model Second model Other models

Optimal strategy

Finally, the optimal strategy obtained is

$$\omega^*(t,y) = \frac{(\mu - r - \gamma \sigma \sigma_e)}{\gamma \sigma^2} \left(1 + \frac{1}{a_1 y} \left[1 - \exp\{-a_1(T-t)\} \right] \right) + \frac{\sigma_e}{\sigma}.$$

æ

First model Second model Other models

Results

Figure: Optimal strategy as a function of time and for different ratios of initial wealth/initial labor income

$$r = 0.02, \ \gamma = 1.1, \ \mu = 0.07, \ \mu_e = 0.01, \ \sigma = 0.2, \ \sigma_e = 0.05, \ e = 0.05, \ e$$

First model Second model Other models

The utility function

We also used a more realistic utility function (HARA). It sets a target \hat{x} in the final wealth

We find the optimal strategy ω^{*}_t that maximizes utility from terminal wealth, this is,

$$v(t, x, e) = \max_{\omega_t} \mathbb{E}\left[\frac{(X_T - \hat{x})^{1-\gamma}}{1-\gamma} | X_0 = x, e_o = e\right]$$

イロン イヨン イヨン イヨン

First model Second model Other models

The results

• We obtained explicit solution for the case $\rho = \pm 1$

<ロ> (四) (四) (三) (三) (三) (三)

First model Second model Other models

- We obtained explicit solution for the case $\rho = \pm 1$
- Monte Carlo simulations and numerical solution of the PDE is under development
