Likelihood Approaches

Preliminaries

.

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

# **Traditional Design-Based Approach**

- Strategies (design and estimation) that appeared reasonable were entertained (accounting for costs). Relative properties carefully studied by analytical and/or empirical methods, mainly through comparison of MSE and anticipated MSE under plausible models
- Design unbiasedness not insisted upon because it "often results in much larger MSE than necessary". Instead, design consistency is deemed necessary for large samples
- Working models used to obtain efficient design-consistent estimators: model-assisted, GREG estimators

Preliminaries ○●	Likelihood Approaches	Empirical Likelihood	Pseudo Empirical Likelihood	Additional Remarks
Unified	Theory			

- Finite population:  $U = \{1, 2, \cdots, N\}$
- Sampling design: s, p(s)
- Sample data:  $\{(i, y_i), i \in s\}$
- Godambe class: Estimator of population total  $Y = \sum_{i=1}^{N} y_i$  uses weights  $d_i(s)$  that may depend on both *i* and *s*

$$\hat{Y} = \sum_{i \in s} d_i(s) y_i$$

• **Theorem**: BLUE of *Y* does not exist in the Godambe class even for simple random sampling.

minaries Likelih

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

#### Non-Parametric Likelihood

- Parameter vector ỹ = (ỹ<sub>1</sub>, · · · , ỹ<sub>N</sub>)'; labels *i* Sample data: {(*i*, y<sub>i</sub>), *i* ∈ s} minimal sufficient
- Godambe (1966) likelihood function:

$$L(\tilde{\mathbf{y}}) = \begin{cases} p(s), \text{ if sample data consistent with } \tilde{\mathbf{y}} \\ 0, \text{ otherwise} \end{cases}$$

• Godambe likelihood is **uninformative**: all possible non-observed  $y_i$ ,  $i \notin s$  lead to the same (flat) likelihood.

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

#### Non-Parametric Likelihood (Cont'd)

Resolution I: Bayesian route (Ericson, 1969)
 Specify an informative (exchangeable) prior distribution:
 Given a joint N-dimensional prior on y with pdf g(y) and assume the sampling design is independent of y, the posterior density is given by

$$h(\tilde{\mathbf{y}}|y_i, i \in s) = \begin{cases} g(\tilde{\mathbf{y}})/g(\tilde{\mathbf{y}}_s) & \text{if } y_i = \tilde{y}_i \text{ for } i \in s, \\ 0 & \text{otherwise}, \end{cases}$$

- Problems:
  - How to specify  $g(\tilde{y})$ ?
  - Posterior inferences are independent of the sampling design, usually invalid under the design-based frameowrk

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

## Non-Parametric Likelihood (cont'd)

- Resolution II: Likelihood route (Hartley and Rao, 1968) Ignore certain aspects of data. For example, for SRS suppress labels *i* and use  $(y_i, i \in s)$ . Likelihood now becomes informative and inference depends on the sample design.
- C. R. Rao (1970): "In situations where the full likelihood does not satisfy our purpose, we may have to depend on a statistic T which for every observed value supplies information (however poor it may be) on parameters of interest. Unfortunately, no unique choice of T may be possible."

# Preliminaries Likelihood Approaches Empirical Likelihood Pseudo Empirical Likelihood Additional Remarks Scale-Load Approach (Hartley and Rao, 1968): SRSWOR

- Finite set of known scale points  $y_1^*, \dots, y_D^*$  with scale loads  $N_1, \dots, N_D$
- Population mean  $\bar{Y} = \sum_{j=1}^{D} p_j y_j^*$  where  $p_j = N_j/N$ Sample scale loads  $n_1, \dots, n_D$
- Likelihood function  $L(N_1, \dots, N_D)$  is hypergeometric likelihood with support on  $n_j > 0$   $(j = 1, \dots, d)$ :  $\prod_{j=1}^d {N_j \choose n_j}$
- For SRS with replacement,  $L(p_1, \dots, p_d)$  reduces to multinomial likelihood, now popularly known as empirical likelihood (Owen, 1988)

 Additional Remarks

 Observations
 Observations
 Observations
 Observations
 Observations

#### • $y_1, \dots, y_n$ IID with CDF F(t); Empirical likelihood function

$$L(\boldsymbol{p}) = \prod_{i=1}^{n} p_i$$

12/34

Maximizing  $L(\mathbf{p})$  subject to  $p_i > 0$  and  $\sum_{i=1}^n p_i = 1$  gives  $\hat{p}_i = 1/n$  $\hat{F}(t) = \sum_{i=1}^n \hat{p}_i I(y_i \le t) = F_n(t)$ 

#### **Empirical Likelihood (Cont'd)**

• Owen (1988): Empirical likelihood ratio statistic for  $\mu = \int y dF(y)$ 

$$R(\mu) = \max\left\{\prod_{i=1}^{n} (np_i) \mid \sum_{i=1}^{n} p_i y_i = \mu, \sum_{i=1}^{n} p_i = 1\right\}$$

 $-2\log R(\mu)$  is asymptotically distributed as  $\chi_1^2$ 

- EL ratio confidence intervals: Shape and orientation of CI determined entirely by the data; CI are range preserving and transformation respecting
- Qin and Lawless (1994): Estimating equations and EL; side information; additional constraints

#### **Empirical Likelihood (Cont'd)**

• Chen and Qin (1993): EL for survey data under simple random sampling Maximum EL estimators  $\bar{K} = N^{-1} \sum_{i=1}^{N} N^{-1}$ 

Maximum EL estimator of  $\overline{Y} = N^{-1} \sum_{i=1}^{N} y_i$  is given by  $\hat{Y}_{EL} = \sum_{i \in s} \hat{p}_i y_i$ , where  $\hat{p}_i$  maximize

$$l(\boldsymbol{p}) = \sum_{i \in s} \log(p_i)$$

subject to

$$\sum_{i\in s} p_i = 1$$
 and  $\sum_{i\in s} p_i \boldsymbol{x}_i = \bar{\boldsymbol{X}}$ 

•  $\overline{Y}_{EL}$  is asymptotically equivalent to the regression estimator under SRS

#### **Empirical Likelihood (Cont'd)**

• Zhong and Rao (2000): EL for stratified simple random sampling

$$l(\boldsymbol{p}) = \sum_{h=1}^{L} \sum_{i \in s_h} \log(p_{hi})$$

Constraints:

$$\sum_{i \in s_h} p_{hi} = 1 \ (h = 1, \cdots, L) \text{ and } \sum_{h=1}^L W_h \sum_{i \in s_h} p_{hi} \mathbf{x}_{hi} = \bar{\mathbf{X}}$$

• Maximum EL estimator of  $\overline{Y}$  is asymptotically equivalent to optimal regression estimator

ikelihood Approaches

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood •00000000000 Additional Remarks

## **Pseudo Empirical Likelihood**

- Design-based inference using complex survey data
   {(y<sub>i</sub>, x<sub>i</sub>), i ∈ s}; π<sub>i</sub> = P(i ∈ s), π<sub>ij</sub> = P(i, j ∈ s); d<sub>i</sub> = 1/π<sub>i</sub>
- Pseudo empirical log-likelihood (PEL) function (Chen and Sitter, 1999)

$$l(\boldsymbol{p}) = \sum_{i \in s} d_i \log(p_i)$$

- $l(\mathbf{p})$  is the Horvitz-Thompson estimator of the census empirical log-likelihood function  $l_N(\mathbf{p}) = \sum_{i=1}^N \log(p_i)$
- Maximum PEL estimator  $\hat{Y}_{PEL} = \sum_{i \in s} \hat{p}_i y_i$ , where  $\hat{p}_i$  maximize  $l(\mathbf{p})$  subject to

$$\sum_{i\in s}p_i=1 \quad ext{and} \quad \sum_{i\in s}p_ioldsymbol{x}_i=oldsymbol{ar{X}}\,,$$

is asymptotically equivalent to the generalized regression (GREG) estimator of  $\overline{Y}$ 

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

・ロト ・回 ト ・ ヨト ・ ヨト … ヨ

20/34

Additional Remarks

# Pseudo Empirical Likelihood (Cont'd)

- The PEL function of Chen and Sitter does not involve  $\pi_{ij}$
- PEL function adjusted by the design effect (Wu and Rao, 2006)

$$l(\boldsymbol{p}) = n^* \sum_{i \in s} \tilde{d}_i(s) \log(p_i) \,,$$

where  $n^* = n/\text{deff}$  (effective sample size), "deff" is the design effect and  $\tilde{d}_i(s) = d_i / \sum_{i \in s} d_i$ 

• Under simple random sampling with replacement,  $l(\mathbf{p}) = \sum_{i \in s} \log(p_i)$ 

ikelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

#### Pseudo Empirical Likelihood (Cont'd)

• PEL ratio function of  $\theta = \bar{Y}$ 

$$r(\theta) = n^* \sum_{i \in s} \tilde{d}_i(s) \log(\hat{p}_i(\theta)) - n^* \sum_{i \in s} \tilde{d}_i(s) \log(\hat{p}_i)$$

 $\hat{p}_i(\theta)$  subject to the additional parameter constraint

$$\sum_{i\in s} p_i y_i = \theta$$

- $-2r(\theta)$  converges in distribution to the  $\chi_1^2$  random variable (Wu and Rao, 2006)
- $(1 \alpha)$ -level PEL ratio confidence interval on  $\overline{Y}$

$$\mathcal{C} = \left\{ \theta \mid -2r(\theta) \le \chi_1^2(\alpha) \right\}$$

		EL	95.2	2.7	2.1	0.115

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

# **PEL: Multiple Surveys**

• Two independent surveys

$$\{(y_i, \mathbf{x}_i), i \in s_1\}$$
 and  $\{(y_i, \mathbf{x}_i), i \in s_2\}$ 

• Joint PEL function (Rao and Wu, 2005)

$$l(\boldsymbol{p}_1, \boldsymbol{p}_2) = n_1^* \sum_{i \in s_1} \tilde{d}_{i1}(s_1) \log(p_{i1}) + n_2^* \sum_{i \in s_2} \tilde{d}_{i2}(s_2) \log(p_{i2})$$

- Maximum PEL estimator  $\hat{Y}_{PEL} = \sum_{i \in s_1} \hat{p}_{i1} y_i = \sum_{i \in s_2} \hat{p}_{i2} y_i$ is asymptotically optimal
- PEL ratio confidence intervals available
- Very flexible in using auxiliary information through added constraints

ies Likelihood A 0000

celihood Approaches

Empirical Likelihood 000000 Pseudo Empirical Likelihood

Additional Remarks

## **PEL: Multiple Frame Surveys**

- Multiple sampling frames: each of them can be incomplete; together they cover the entire finite population
- Dualframe A and B:  $U = a \cup ab \cup b$  (three domains)
- *Q*-frame survey samples:  $\{(y_i, \mathbf{x}_i), i \in s_q\}, q = 1, \cdots, Q$
- Multiplicity-based PEL function (Rao and Wu, 2009)

$$l_M(\boldsymbol{p}_1,\cdots,\boldsymbol{p}_Q) = \frac{n_M}{\hat{N}_M} \sum_{q=1}^Q \sum_{i \in s_q} \frac{d_{qi}}{m_{qi}} \log(p_{qi})$$

 $-n_M = \sum_{q=1}^Q n_q;$   $n_q$ : *q*th frame sample size  $-\hat{N}_M = \sum_{q=1}^Q \sum_{i \in s_q} d_{qi}/m_{qi}$   $-d_{qi}$ : *q*th frame sampling weights  $-m_{qi}$ : number of frames to which unit *i* on frame *q* belongs

< □ > < □ > < □ > < □ > < □ > < Ξ > < Ξ > = Ξ

ikelihood Approaches

Empirical Likelihood 000000 Pseudo Empirical Likelihood

Additional Remarks

## **PEL: Multiple Frame Surveys**

- Pooling together the Q samples into a single one without removing duplicated units
- Auxiliary information can be used through added constraints
- PEL ratio function for  $\bar{Y}$  is asymptotically  $\chi_1^2$
- Excellent performance in estimating population proportions of rare items

ikelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

# **Bayesian Pseudo Empirical Likelihood**

- Three issues:
  - (i) likelihood function for complex survey data
  - (ii) prior distribution
  - (iii) posterior distribution providing valid inference under design-based set-up
- Bayesian PEL formulation I: Profile PEL function on  $\theta = \overline{Y}$  and flat prior on  $\theta$
- Bayesian PEL formulation II: PEL function  $l(p_1, \dots, p_n)$  and Dirichlet-Haldane prior on  $(p_1, \dots, p_n)$
- Both formulations provide posterior inferences which are valid under the design-based set-up (Rao and Wu, 2010)

• Profile PEL for  $\theta$ 

$$l_{PEL}(\theta) = n^* \sum_{i \in s} \tilde{d}_i(s) \log \hat{p}_i(\theta) \,,$$

where the  $\hat{p}_i(\theta)$  maximize  $\sum_{i \in s} \tilde{d}_i(s) \log p_i$  subject to

$$\sum_{i \in s} p_i = 1$$

$$\sum_{i \in s} p_i y_i = \theta$$

$$\sum_{i \in s} p_i \mathbf{x}_i = \bar{\mathbf{X}}.$$

< □ > < □ > < □ > < Ξ > < Ξ > < Ξ > Ξ のQ(?) 27/34

Preliminaries 00	Likelihood Approaches	Empirical Likelihood	Pseudo Empirical Likelihood	Additional Remarks
Bayesia	<b>n PEL for</b> $\theta$	$= \overline{Y}$		

• Posterior distribution of  $\theta$  under noninformative prior  $p(\theta) \propto 1$ 

$$\pi(\theta|\mathbf{y},\mathbf{x}) = c(\mathbf{y},\mathbf{x}) \exp\left\{-n^* \sum_{i \in s} \tilde{d}_i(s) \log(1+\boldsymbol{\lambda}'\boldsymbol{u}_i)\right\}$$

where  $\lambda$  solves

$$g(\boldsymbol{\lambda}) = \sum_{i \in s} \frac{\tilde{d}_i(s)\boldsymbol{u}_i}{1 + \boldsymbol{\lambda}' \boldsymbol{u}_i} = \boldsymbol{0}$$

< □ > < □ > < □ > < □ > < □ > < □ > < Ξ > < Ξ > □ Ξ

28/34

with  $\boldsymbol{u}_i = (y_i - \theta, \boldsymbol{x}'_i - \bar{\boldsymbol{X}}')'$ 

Likelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

### **Bayesian PEL for** $\theta = \overline{Y}$

- The posterior distribution  $\pi(\theta | \mathbf{y}, \mathbf{x})$  is asymptotically normal
- The posterior mean is asymptotically equivalent to the GREG estimator of  $\bar{Y}$  and hence is design consistent
- The posterior variance matches the design-based variance of the GREG estimator
- Posterior inferences are valid under the design-based framework

ikelihood Approaches

Empirical Likelihood

Pseudo Empirical Likelihood

Additional Remarks

#### **Bayesian PEL based on** $(p_1, \cdots, p_n)$

- Treat  $p_1, \cdots, p_n$  as parameters
- The pseudo empirical log-likelihood

$$l_{PEL}(\boldsymbol{p}) = n^* \sum_{i \in s} \tilde{d}_i(s) \log p_i$$

• The pseudo empirical likelihood

$$L_{PEL}(\boldsymbol{p}) = \exp\{l_{PEL}(\boldsymbol{p})\} = \prod_{i \in s} p_i^{\gamma_i}$$

$$\gamma_i = n^* \tilde{d}_i(s)$$

With the Dirichlet-Haldane prior π(**p**) ∝ ∏p<sub>i</sub><sup>-1</sup>, the posterior distribution of (p<sub>1</sub>, · · · , p<sub>n</sub>) is also Dirichlet:

$$\pi(p_1,\cdots,p_n|s) \propto \prod_{i=1}^n p_i^{\gamma_i-1}$$

# **Bayesian PEL based on** $(p_1, \cdots, p_n)$

- This is a generalization of Hartley-Rao scale-load method to an arbitrary sampling design
- The posterior distribution of  $\theta = \overline{Y}$  is the distribution of  $\theta = \sum_{i \in s} p_i y_i$  based on the Dirichlet distribution for  $(p_1, \dots, p_n)$
- Posterior mean and variance of  $\theta$  match the design-based GREG estimator and its variance
- Valid posterior inference for the mean under the design
- May have an advantage in handling other type of parameters such as quantiles
