April 2011

- Introduction: Heat conduction in $1D$ systems.
 - Disordered harmonic chains
 - Ordered anharmonic chains
 - Disordered anharmonic chains: effect of interactions on localization.
- Stochastic models of heat conduction.
- Analytically tractable model to study effects of interactions on localization .
 - Exact results.
 - Numerical results.
- Discussion.

Fourier's Law

For small $\Delta T = T_L - T_R$ and system size L :

$$\text{Fourier's law implies : } J \sim \kappa \frac{\Delta T}{L}$$

The thermal conductivity κ is expected to be an intrinsic material property.

- Fourier's law is not generally valid in low-dimensional systems . κ depends on system size L .
- Necessary and sufficient conditions for validity of Fourier's law ?
Role of anharmonicity, disorder and dimensionality.

Bonetto, Lebowitz, Rey-Bellet, Math. Phys. (2000) .

Lepri, Livi, Politi, Phys. Rep. (2003) .

Dhar , Adv. Phys. (2008) .

Disordered Harmonic systems: Results in 1D

Exact expression for nonequilibrium heat current [“Landauer-like” formula for phonons.]
In classical case:

$$J = \frac{k_B \Delta T}{2\pi} \int_0^\infty d\omega T(\omega),$$

where $T(\omega)$ is the phonon transmission function.

[Casher and Lebowitz (1971), Rubin and Greer (1971), Dhar and Roy (2006)].

Anderson localization implies: $T(\omega) \sim e^{-L/\ell(\omega)}$ with $\ell(\omega) \sim 1/\omega^2$ for $\omega \rightarrow 0$.

Disordered Harmonic systems: 1D

Hence frequencies $\omega \lesssim L^{-1/2}$ “do not see” the randomness and can carry current. These are the ballistic modes.

$$\text{Hence } J \sim \int_0^{L^{-1/2}} T(\omega) d\omega.$$

Form of $T(\omega)$ (at small ω) depends on boundary conditions.

$$\begin{array}{ll} \text{Fixed BC:} & T(\omega) \sim \omega^2 \quad J \sim 1/L^{3/2} \\ \text{Free BC:} & T(\omega) \sim \omega^0 \quad J \sim 1/L^{1/2} \end{array}$$

If all sites are pinned then low frequency modes are cut off. Hence we get:

$$\text{Pinned case : } J \sim e^{-L/\ell}.$$

Matsuda, Ishii, Rubin/Greer, Casher/Lebowitz, Dhar.

Exact results: Verheggen (1979), Ajanki / Huveneers (2010).

One dimensional disordered harmonic chain

- Almost all normal modes of the chain are localized and their amplitude at the boundaries is exponentially small (in L) leading to transmission decaying exponentially.
- Low frequency modes are extended and transmit energy.
- No Fourier's law: Strong boundary condition dependence.
- Heat insulator in pinned case.

One-dimensional systems with nonintegrable interactions

Momentum conserving system: FPU - model

$$H = \sum_{\ell=1}^N \frac{p_{\ell}^2}{2m} + \sum_{\ell=1}^{N+1} \left[k_2 \frac{(q_{\ell} - q_{\ell-1})^2}{2} + k_3 \frac{(q_{\ell} - q_{\ell-1})^3}{3} + \lambda \frac{(q_{\ell} - q_{\ell-1})^4}{4} \right] .$$

Momentum non-conserving system: ϕ^4 - model

$$H = \sum_{\ell=1}^N \left[\frac{p_{\ell}^2}{2m} + k_o \frac{q_{\ell}^2}{2} \right] + \sum_{\ell=1, N+1} k_2 \frac{(q_{\ell} - q_{\ell-1})^2}{2} + \sum_{\ell=1}^N \lambda \frac{q_{\ell}^4}{4} .$$

Simulations:

- Momentum conserving: $\kappa \sim L^{1/3}$ ($L^{2/5}$, $L^{1/2}$?) .
- Momentum nonconserving (pinned case): $\kappa \sim L^0$

Theory

- Momentum conserving:

MC (Lepri, Livi, Politi, Delfini) $\kappa \sim L^{1/3}, L^{1/2}$ (odd, even)

RG (Narayan, Ramaswamy) $\kappa \sim L^{1/3}$ (universal)

Kinetic theory (Pereverzev, Lukkarinen, Spohn) $\kappa \sim L^{2/5}$. (even)

- Momentum nonconserving (pinned case): $\kappa \sim L^0$.

- Long wavelength modes lead to slow decay of current-current correlations and hence to anomalous transport.

- Value of current depends on BCs, but exponents do not.

Effect of interaction on localization (Numerical results)

(A) Disordered FPU model (Dhar and Saito)

$$H = \sum_{\ell=1,N} \frac{p_{\ell}^2}{2m_{\ell}} + \sum_{\ell=1,N+1} k \frac{(q_{\ell} - q_{\ell-1})^2}{2} + \lambda \frac{(q_{\ell} - q_{\ell-1})^4}{4}.$$

(B) Disordered ϕ^4 model (Dhar and Lebowitz)

$$H = \sum_{\ell=1,N} \left[\frac{p_{\ell}^2}{2m_{\ell}} + k_0 \frac{q_{\ell}^2}{2} \right] + \sum_{\ell=1,N+1} k \frac{(q_{\ell} - q_{\ell-1})^2}{2} + \sum_{\ell=1,N} \lambda \frac{q_{\ell}^4}{4}.$$

$$\{m_{\ell}\} = [m - \Delta, m + \Delta].$$

Disorder $\rightarrow \Delta$

Anharmonicity $\rightarrow \lambda$.

Simulations:

Case (A) $\lambda = 0 : \kappa \sim L^{1/2}, L^{-1/2}$ $\lambda > 0 : \kappa \sim L^{1/3}.$

Case (B) $\lambda = 0 : \kappa \sim e^{-cL},$ $\lambda > 0 : \kappa \sim L^0.$

Numerical results: Pinned case

Dhar/Lebowitz (2008)

Dramatic transition: $e^{-cN/\ell} \rightarrow \frac{1}{N}$
for small amount of interaction.

$$\kappa \sim (\lambda T)^a$$

$$a = 1/2 \quad [a = 4 - \text{Flach } et al (2011)]$$

- **Many-body localization** — In the $\lambda - \Delta$ plane, is there a conductor-insulator transition ?
- **Transport mechanism**: Destruction of localization ?, Hopping of energy between localized states ?
- Small λ behaviour of $\kappa(\lambda)$.

Look at analytically tractable models to address these questions.

MOTIVATION

- Analytically tractable.
- Physical relevance: one hopes that they effectively mimic anharmonicity and environmental degrees of freedom.

Purely Stochastic dynamics (Local energy conservation)

- Kipnis-Marchioro-Presutti model for heat conduction in harmonic oscillator chain .
- Creutz model for heat conduction in Ising model .

Hamiltonian + Stochastic dynamics

- Self-Consistent Reservoirs (Momentum Non-conserving)
(Bolsterli, Rich, Visscher)
- Local momentum exchange dynamics (Both momentum conserving and non-conserving)
(Basile, Bernardin, Olla)
(Delfini, Lepri, Livi, Politi, Mejia-Monasterio)
(Bernardin)

Self-consistent reservoirs

$$\begin{aligned}
 m_1 \ddot{q}_1 &= -\Phi_{1m} q_m + [-\gamma \dot{q}_1 + (2\gamma T_L)^{1/2} \eta_1(t)] + [-\gamma'_1 \dot{q}_1 + (2\gamma'_1 T'_1)^{1/2} \zeta_1(t)] \\
 m_\ell \ddot{q}_\ell &= -\Phi_{\ell,m} q_m + [-\gamma'_\ell \dot{q}_\ell + (2\gamma'_\ell T'_\ell)^{1/2} \zeta_\ell(t)] \quad \ell = 2, \dots, N-1, \\
 m_N \ddot{q}_N &= -\Phi_{Nm} q_m + [-\gamma \dot{q}_N + (2\gamma T_R)^{1/2} \eta_N(t)] + [-\gamma'_N \dot{q}_N + (2\gamma'_N T'_N)^{1/2} \zeta_N(t)].
 \end{aligned}$$

Self-consistency condition: Zero net current into side reservoirs.

$$\langle p_\ell^2 / m_\ell \rangle = T'_\ell, \quad \ell = 1, 2, \dots, N.$$

- Model introduced by Bolsterli, Rich, Visscher (1970):
“Simulation of nonharmonic interactions in a crystal by self-consistent reservoirs”
- Ordered harmonic chain: solved exactly by Bonetto, Lebowitz and Lukkarinen (2004).
Fourier's law satisfied and κ is finite.
- Disordered harmonic chain: numerically studied by Rich and Visscher.
 - Finite conductivity, independent of boundary conditions.
 - **CONJECTURE**: In the limit of vanishing coupling to side reservoirs, the conductivity $\kappa \rightarrow$ a finite value.
NOTE: In absence of side-reservoirs:
 $\kappa \rightarrow \infty$ free BCs.
 $\kappa \rightarrow 0$ fixed BCs.
- Momentum non-conserving. Energy conserved, on average.

Momentum and energy conserving models

- Basile, Bernardin, Olla: 3-particle collisions

$$p_{\ell-1} + p_{\ell} + p_{\ell+1} = \text{constant}$$

$$p_{\ell-1}^2 + p_{\ell}^2 + p_{\ell+1}^2 = \text{constant}.$$

- Delfini, Lepri, Livi, Politi, Mejia-Monasterio: 2 particle collisions

$$p_{\ell} \leftrightarrow p_{\ell+1} .$$

- Ordered harmonic chain: $\kappa \sim L^{1/2}$.
[numerical and analytical results]

Energy conserving (Momentum non-conserving)

- Bernardin: 2-particle collisions

$$p_{\ell}^2 + p_{\ell+1}^2 = \text{constant}.$$

- Present study: Momentum flip model

$$p_{\ell} \leftrightarrow -p_{\ell} .$$

- Ordered and disordered harmonic chain: $\kappa \sim L^0$.
[numerical and analytical results]

Definition of model studied by us

$$\begin{aligned} H &= \sum_{\ell=1,N} \left[\frac{p_{\ell}^2}{2m_{\ell}} + k_o \frac{q_{\ell}^2}{2} \right] + \sum_{\ell=2,N} k \frac{(q_{\ell} - q_{\ell-1})^2}{2} + k' \left[\frac{q_1^2}{2} + \frac{q_N^2}{2} \right] \\ &= \frac{1}{2} \left[p \hat{M}^{-1} p + q \hat{\Phi} q \right], \end{aligned}$$

$k_o = 0$: Unpinned case Free BC ($k' = 0$), Fixed BC ($k' > 0$)

$k_o > 0$: Pinned case .

The system's time evolution has:

- ❶ A deterministic part described by the Hamiltonian above.
- ❷ A momentum flipping noise at all sites: transition $p_{\ell} \rightarrow -p_{\ell}$ occurs with a rate λ .
- ❸ Particles at the boundaries $\ell = 1$ and $\ell = N$ which are attached to Langevin heat baths at temperatures T_L and T_R respectively.

- Non-equilibrium definition:

$$\kappa = \lim_{L \rightarrow \infty} \frac{\langle J \rangle L}{\Delta T}$$

J = Current density .

- From Green-Kubo formulation:

$$\kappa_{GK} = \lim_{z \rightarrow 0} \lim_{L \rightarrow \infty} \frac{1}{LT^2} \int_0^\infty dt e^{-zt} \langle \mathcal{J}(0) \mathcal{J}(t) \rangle .$$

\mathcal{J} = Total current .

Master equation for time evolution

Let $x = (q_1, q_2, \dots, q_N, p_1, p_2, \dots, p_N) = (x_1, x_2, \dots, x_{2N})$

$P(x, t)$: phase-space probability distribution .

Master equation:

$$\frac{\partial P(x)}{\partial t} = \sum_{\ell, m} \hat{a}_{\ell, m} x_m \frac{\partial P}{\partial x_{\ell}} + \sum_{\ell, m} \frac{\hat{d}_{\ell, m}}{2} \frac{\partial^2 P}{\partial x_{\ell} \partial x_m} + \lambda \sum_{\ell} [P(\dots, -p_{\ell}, \dots) - P(\dots, p_{\ell}, \dots)] ,$$

$$\text{where } \hat{a} = \begin{pmatrix} 0 & -\hat{M}^{-1} \\ \hat{\Phi} & \hat{M}^{-1} \hat{\Gamma}^{-1} \end{pmatrix} \quad \hat{d} = \begin{pmatrix} 0 & 0 \\ 0 & 2 \hat{T} \hat{\Gamma} \end{pmatrix} .$$

$$\hat{T}_{\ell, \ell} = T_L \delta_{\ell, 1} + T_R \delta_{\ell, N}$$

$$\hat{\Gamma}_{\ell, \ell} = \gamma (\delta_{\ell, 1} + \delta_{\ell, N})$$

Equations for pair-correlations

Define pair-correlation matrix:

$$\hat{c} = \begin{pmatrix} \hat{u} & \hat{z} \\ \hat{z}^T & \hat{v} \end{pmatrix}, \text{ where } \hat{u}_{\ell,m} = \langle q_{\ell} q_m \rangle, \hat{v}_{\ell,m} = \langle p_{\ell} p_m \rangle, \hat{z}_{\ell,m} = \langle q_{\ell} p_m \rangle.$$

Closed equation of motion for \hat{c} :

$$\frac{d\hat{c}}{dt} = -\hat{a}\hat{c} - \hat{c}\hat{a}^T + \hat{d} + \left(\frac{d\hat{c}}{dt} \right)_{col}.$$

Term from flip dynamics is given by:

$$\left(\frac{d\hat{c}}{dt} \right)_{col} = -2\lambda \begin{pmatrix} 0 & \hat{z} \\ \hat{z}^T & 2(\hat{v} - \hat{v}_D) \end{pmatrix}, \text{ where } [\hat{v}_D]_{\ell,\ell} = \hat{v}_{\ell,\ell} = \langle p_{\ell}^2 \rangle.$$

In steady state $d\hat{c}/dt = 0$ gives:

$$\hat{a}\hat{c} + \hat{c}\hat{a}^T - \left(\frac{d\hat{c}}{dt} \right)_{col} = \hat{d}$$

With $\gamma'_{\ell} = 2 \lambda m_{\ell}$ and $\langle p_{\ell}^2 / m_{\ell} \rangle = T'_{\ell}$, the above equations are identical to the correlation equations for model with self-consistent reservoirs.

- Steady state current given by $J = k \langle x_\ell v_{\ell+1} \rangle$. Exact solution available for ordered case – BLL (2004).
- Closed equations for correlation in all orders. However **NON-GAUSSIAN** unlike self-consistent reservoir model .
- $N^2 + N(N + 1)$ linear equations for same number of unknown variables . Accurate numerical solution possible for disordered case and both steady state current and temperature profiles can be obtained.

Green-Kubo conductivity

No Langevin baths for end-particles, periodic BCs. Master equation is:

$$\begin{aligned}\frac{\partial P(x)}{\partial t} &= LP(x), \\ \text{where } L &= A + \lambda S, \\ AP(x) &= \sum_{\ell=1}^N \left[-\frac{p_{\ell}}{m_{\ell}} \frac{\partial P(x)}{\partial q_{\ell}} + \sum_{m=1}^N \Phi_{\ell,m} q_m \frac{\partial P(x)}{\partial p_{\ell}} \right] && \text{Hamiltonian part,} \\ SP(x) &= \sum_{\ell} [P(\dots, -p_{\ell}, \dots) - P(\dots, p_{\ell}, \dots)] && \text{Stochastic part.}\end{aligned}$$

The Green-Kubo thermal conductivity κ_{GK} is:

$$\begin{aligned}\kappa_{GK} &= \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} \frac{1}{NT^2} \int_0^{\infty} dt e^{-zt} \langle \mathcal{J}(0) \mathcal{J}(t) \rangle \\ &= \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} \frac{1}{NT^2} \langle \mathcal{J} (z - L)^{-1} \mathcal{J} \rangle.\end{aligned}$$

Green-Kubo conductivity

The total current which is carried entirely by the Hamiltonian part can be written in the following form:

$$\mathcal{J} = \frac{k}{2} \sum_{\ell=1}^N \frac{p_{\ell}}{m_{\ell}} (q_{\ell+1} - q_{\ell-1})$$

With this and the forms of A and S it follows:

$$\begin{aligned} A\mathcal{J}P_{eq} &= \sum_{\ell,j} \frac{\Phi_{\ell,j} q_j}{m_{\ell}} (q_{\ell+1} - q_{\ell-1}) P_{eq} \\ \text{and } S\mathcal{J}P_{eq} &= -2\mathcal{J}P_{eq} . \end{aligned}$$

Ordered case: $A\mathcal{J}P_{eq} = 0$.

Ordered case (exact expression for κ).

$$\kappa_{GK} = \lim_{z \rightarrow 0} \lim_{N \rightarrow \infty} \frac{1}{T^2 N} \int dx \mathcal{J} \frac{1}{z + 2\lambda} \mathcal{J} P_{eq} = \lim_{N \rightarrow \infty} \frac{\langle \mathcal{J}^2 \rangle}{2\lambda T^2 N}.$$

$$\kappa_{GK} = \frac{kD}{8\lambda m}, \quad \text{where } D = \frac{4k}{2k + k_o + [(k_o)(4k + k_o)]^{1/2}}.$$

Same as result for κ for self-consistent reservoirs.– BLL (2004)

Disordered case (lower and upper bounds):

$$\frac{kD}{8\lambda[m](1 + k \frac{[1/m] - 1/[m]}{4\lambda^2 D})} \leq [\kappa_{GK}] \leq \frac{kD}{8\lambda} \left[\frac{1}{m} \right]$$

– Bernardin (2008)

Motivations:

- Bounds show that κ_{GK} finite for any finite λ . For $\lambda \rightarrow 0$ — $\kappa_{LB} \sim \lambda$, $\kappa_{UB} \sim 1/\lambda$.
Not clear what happens at $\lambda \rightarrow 0$.
 - Comparing κ (from NESS) with κ_{GK} .
-
- Apply temperature difference ΔT and compute J for different system sizes. Use two methods:
 - From numerical solution of steady state equations for pair-correlations .
 - Direct non-equilibrium simulations .
 - Plot $\kappa_N = JN/\Delta T$ and check if this saturates for large N . Hence obtain κ .
 - Study two different cases
 - (i) Unpinned system with fixed and free BCs .
 - (ii) Pinned system .

Numerical results: Pinned case

$JN/\Delta T$ - versus - system size
for different values of λ

Conductivity-versus- λ
 κ follows the lower bound κ_{GK} .
 $\kappa \sim 1/\lambda$ at large λ .
 $\kappa \sim \lambda$ at small λ .

Heuristic argument for small λ behaviour .

- For $\lambda = 0$, all phonon modes are localized within length-scales $\ell_L \sim \frac{k}{k_0} \left(\frac{m}{\Delta}\right)^2$.
- For small λ , mean free path of phonons $\ell \sim 1/\lambda$.
Since $\ell \gg \ell_L$, localized states are not destroyed completely.
- There is diffusion of energy between the localized states with a diffusion constant $\sim \ell_L^2 \lambda$. Hence:

$$\kappa \sim \frac{k^2 m^4}{k_0^2 \Delta^4} \lambda .$$

This is consistent with numerical data .

Numerical results: Unpinned case

$JN/\Delta T$ - versus - system size for
different values of λ
for free and fixed BCs.

κ - versus - λ
 $\kappa \sim 1/\lambda^{1/2}$ at small λ .
 $\kappa \sim 1/\lambda$ at large λ .

Unpinned case: discussion

- κ is independent of BCs for all $\lambda > 0$. Diffusive heat transport.

- Need large N to reach the correct asymptotic diffusive limit.

Effective mean free path $\ell \sim 1/\lambda$.

To see diffusion of the low frequency ballistic modes, one needs $N \gtrsim \ell$ or $N \gtrsim 1/\lambda$.

Heuristic argument for small λ behaviour:

- In absence of noise, localization length $\ell_L \sim 1/\omega^2$.
- Hence all modes with $\ell_L < \ell$ or $\omega > \lambda^{1/2}$ stay localized.
- The low frequency modes $0 < \omega < \lambda^{1/2}$ become diffusive with mean free paths $\sim 1/\lambda$ thus resulting in a conductivity:

$$\kappa \sim \lambda^{1/2} \times \frac{1}{\lambda} \sim \frac{1}{\lambda^{1/2}} .$$

Thus $\kappa \rightarrow \infty$ as $\lambda \rightarrow 0$ unlike conjecture of Rich/Visscher.

Refn: Dhar, Venkateshan, Lebowitz, PRE **83**, 021108 (2011)

- Analytically tractable model to study effect of interactions in disordered harmonic systems .
- Mapping to model of self-consistent reservoirs and exact bounds for GK conductivity .
- For pinned case exact proof of insulator - conductor transition for arbitrarily small value of λ . Different from many-body localization in quantum systems .
- For $\lambda \rightarrow 0$, $\kappa \sim \lambda$ (pinned case), $\kappa \sim 1/\lambda^{1/2}$ (unpinned case) .
Rigorous proof ?
- NESS: Deviation from Gaussian measure. Does this vanish in the thermodynamic limit ?
