A two-stage approach to relaxation in locally confined hard sphere systems

Thomas Gilbert

Center for Nonlinear Phenomena and Complex Systems
Université Libre de Bruxelles

Workshop on the Fourier Law and Related Topics
April 4-8 2011, Fields Institute, Toronto

Abstract

I will describe the characterization of heat transfer in models of high-dimensional billiards, which capture the properties of materials that possess both the spatial structure of solids and collisional dynamics of gases. I will discuss the conditions under which the heat conductivity of these models can be universally expressed in terms of the frequency of collisions between gas particles. This universality manifests itself when interactions between gas particles are rare, though not necessarily small. The dynamical properties of these models will be analyzed, and the role of dimensionality emphasized.

Brief Survey

Historical Context

Fourier's law (1822) describes the phenomenological relaxation of heat towards a uniform temperature :

$$\partial_t T(x,t) = \partial_x[\kappa \partial_x T(x,t)]$$

The works of Maxwell (1867) and Boltzmann (1872) on the Kinetic Theory of Gases have emphasized the mechanical origin of heat flow.

The Challenge

Can we provide a derivation of this law from first principles in the framework of Hamiltonian mechanics?

Motivation from Material Science

Aerogels are 99.8% air-filled nano-porous materials which are remarkable thermal insulators. They have the spatial structure of solid materials and their kinetics is similar to rarefied gases.

Solid smoke

- ► Solid, gaseous and radiative heat conductions are inhibited
- ► Gas molecules typically collide with the nano-pore walls rather than among themselves
- ► This provides a local equilibration mechanism

Our Perspective

Because of the confining mechanism of gas molecules

local equilibrium (*without energy exchange*) precedes local thermalisation

Two-stage scenario for local thermalisation

Thermal conduction proceeds over three well-separated time scales :

- short time scale $\quad \tau_{\text{wall}}$
- intermediate time scale $\quad \tau_{\text{binary}}$
- long time scale $\quad \tau_{\text{macro}}$

$$\tau_{\text{wall}} \ll \tau_{\text{binary}} \ll \tau_{\text{macro}}$$

This scenario offers the means to deriving Fourier's law!

Diffusive transport at the macroscopic scale

From microscopic to mesoscopic to macroscopic scales

$$p(\mathbf{n}, \mathbf{r}, \mathbf{v}, t) \to p_{\text{leq}}(\mathbf{n}, t) \to P(\mathbf{r}, t)$$

Fokker-Planck equation at macroscopic scale

$$\partial_t P(\mathbf{r}, t) = \mathcal{D} \nabla^2 P(\mathbf{r}, t)$$

with diffusion coefficient

$$\mathcal{D} = \frac{v \delta l^2}{\pi A} = \frac{l^2}{4\tau}$$

This is the Machta Zwanzig approximation

ULB

Statistical evolution

pseudo-Liouville equation for $p(\mathbf{n}, \mathbf{r}, \mathbf{v}, t)$

$$\partial_t p = \left\{ -\mathbf{v} \cdot \partial_\mathbf{r} + \sum_{n=1}^{c} K^{(d)} + \sum_{j=1}^{4} W^{(j)} \right\} p + \sum_{j=1}^{4} J^{(j)} p$$

where

- $-\mathbf{v} \cdot \partial_\mathbf{r}$ is the advection term due to the motion of the particle inside the cell
- the disk collision term $K^{(d)}$ rules the collisions with the fixed discs
- the wall collision term $W^{(j)}$ rules the collisions with the (virtual) flat walls
- the jump term $J^{(j)}$ accounts for the advection of the tracer across the cell boundaries

ULB

Continuous-time random walk

Local equilibrium distribution

$$p_{\text{leq}}(\mathbf{n}, t) = \int \mathrm{d}\tilde{\mathbf{r}} \int \mathrm{d}\tilde{\mathbf{v}} \delta(\tilde{v}^2 - v^2) p(\mathbf{n}, \tilde{\mathbf{r}}, \tilde{\mathbf{v}}, t)$$

changes in time only according to jump events:

$$\partial_t p_{\text{leq}}(\mathbf{n}, t) = \sum_{j=1}^{4} \int \mathrm{d}\tilde{\mathbf{r}} \int \mathrm{d}\tilde{\mathbf{v}} \delta(\tilde{v}^2 - v^2) J^{(j)} p(\mathbf{n}, \tilde{\mathbf{r}}, \tilde{\mathbf{v}}, t)$$

Jump operator (right wall)

$$
\begin{aligned}
J^{(1)} p(\mathbf{n}, \mathbf{r}, \mathbf{v}, t) =\ & v_x \delta(r_x - l/2) \theta(r_y + \delta/2) \theta(\delta/2 - r_y) \theta(v_x) \\
& \times [p(\mathbf{n} + (1,0), \mathbf{r}, -v_x, v_y, t) - p(\mathbf{n}, \mathbf{r}, v_x, v_y, t)]
\end{aligned}
$$

ULB

Continuous-time random walk ct'd

Under the closure approximation

$$p(\mathbf{n}, \tilde{\mathbf{r}}, \tilde{\mathbf{v}}, t) = \frac{1}{\pi A} \delta(\tilde{v}^2 - v^2) p_{\text{leq}}(\mathbf{n}, t)$$

the Liouville equation reduces to a master equation:

$$\partial_t p_{\text{leq}}(\mathbf{n}, t) = \sum_{j=1}^{4} \frac{v\delta}{\pi A} [p_{\text{leq}}(\mathbf{n} + \mathbf{e}_j, t) - p_{\text{leq}}(\mathbf{n}, t)]$$

This is a continuous-time random walk

The waiting-time distribution is exponential with timescale

$$\tau_{\text{J}} = \frac{\pi A}{4v\delta}$$

ULB

Diffusion process

The master equation reduces to a Fokker-Planck equation in the continuum limit $\mathbf{r} = l\mathbf{n}$, $l \to 0$, $v \sim l^{-2}$:
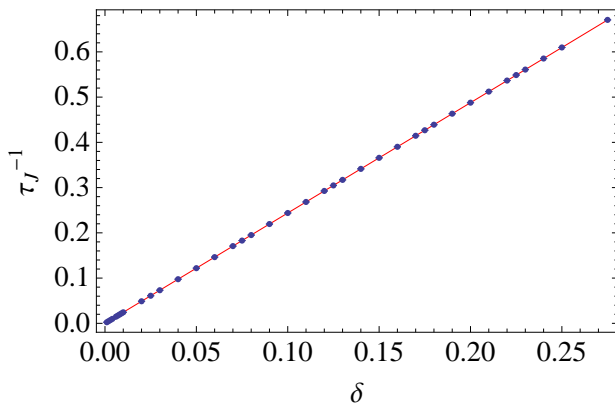

$$p_{\text{leq}}(\mathbf{n}, t) \to P(\mathbf{r}, t)$$

$$\partial_t P(\mathbf{r}, t) = \mathcal{D}\nabla^2 P(\mathbf{r}, t)$$

with the diffusion coefficient

$$\mathcal{D} = \frac{v\delta l^2}{\pi A} = \frac{l^2}{4\tau_{\text{J}}}$$

$$h_{\text{KS}} = \sum_{i=1}^{N} \lambda_i \simeq N \sqrt{\frac{\pi}{4}} \lambda_+$$

ULB

Kolmogorov Sinai Entropy

Outline

Kinetic Theory

The phase-space probability density $p_N(\mathbf{r}_1, \mathbf{v}_1, \ldots, \mathbf{r}_N, \mathbf{v}_N, t)$ evolves according to the pseudo-Liouville equation

$$\partial_t p_N = \sum_{a=1}^{N} \left[-\mathbf{v}_a \cdot \partial_{\mathbf{r}_a} + \sum_{k=1}^{d} K^{(a,k)} \right] p_N + \frac{1}{2} \sum_{a,b=1}^{N} B^{(a,b)} p_N$$

where

▶ $-\mathbf{v}_a \cdot \partial_{\mathbf{r}_a}$ is the advection term due to the motion of the particle a inside its cell;

▶ the wall term $K^{(a,k)}$ is the operator ruling the collisions of particle a on the fixed disc k;

▶ the binary collision term $B^{(a,b)}$ rules the collisions between the particles a and b in neighbouring cells.

ULB

From Deterministic to Stochastic Dynamics

The local equilibrium distribution

$$P_N^{(\text{leq})}(\epsilon_1, \ldots, \epsilon_N, t) \equiv \int \prod_{a=1}^{N} d\mathbf{r}_a d\mathbf{v}_a \, p_N(\{\mathbf{r}_i, \mathbf{v}_i\}, t) \prod_{a=1}^{N} \delta(\epsilon_a - m v_a^2/2)$$

is left unchanged by the advection and wall terms.

We can make a closure approximation to obtain the time-evolution of the local equilibrium distribution

$$\partial_t P_N^{(\text{leq})}(\epsilon_1, \ldots, \epsilon_N, t) =$$
$$\frac{1}{2} \sum_{a,b=1}^{N} \int d\eta \Big[W(\epsilon_a + \eta, \epsilon_b - \eta | \epsilon_a, \epsilon_b) \, P_N^{(\text{leq})}(., \epsilon_a + \eta, ., \epsilon_b - \eta, ., t)$$
$$- W(\epsilon_a, \epsilon_b | \epsilon_a - \eta, \epsilon_b + \eta) \, P_N^{(\text{leq})}(\ldots, \epsilon_a, \ldots, \epsilon_b, \ldots, t) \Big]$$

ULB

Transition Rates (2D dynamics)

The transition rate of the binary collisions of energy transfer η between the neighbouring particles *a* and *b* is given by

$$W(\epsilon_a, \epsilon_b | \epsilon_a - \eta, \epsilon_b + \eta) =$$
$$\frac{2\rho_{\mathrm{m}} m^2}{(2\pi)^2 |\mathcal{L}_{\rho,\rho_{\mathrm{m}}}(2)|} \int \mathrm{d}\phi \, \mathrm{d}\mathbf{R} \int_{\hat{\mathbf{e}}_{ab} \cdot \mathbf{v}_{ab} > 0} \mathrm{d}\mathbf{v}_a \mathrm{d}\mathbf{v}_b \, \hat{\mathbf{e}}_{ab} \cdot \mathbf{v}_{ab}$$
$$\times \delta\left(\epsilon_a - \frac{m}{2} v_a^2\right) \delta\left(\epsilon_b - \frac{m}{2} v_b^2\right)$$
$$\times \delta\left(\eta - \frac{m}{2}[(\hat{\mathbf{e}}_{ab} \cdot \mathbf{v}_a)^2 - (\hat{\mathbf{e}}_{ab} \cdot \mathbf{v}_b)^2]\right)$$

where the volume $|\mathcal{L}_{\rho,\rho_{\mathrm{m}}}(2)| \simeq |\mathcal{B}_\rho|^2$, ϕ is the angle of the unit vector $\hat{\mathbf{e}}_{ab}$ connecting *a* and *b*, and $\mathbf{R}$ their center of mass.

ULB

Transition Rates (2D dynamics)

After proper time renormalization, the kernel can be written in terms of Jacobi elliptic functions K ($\epsilon_b > \epsilon_a$):

$$W(\epsilon_a, \epsilon_b | \epsilon_a - \eta, \epsilon_b + \eta) =$$

$$\sqrt{\frac{2}{\pi^3}} \times \begin{cases} \sqrt{\frac{1}{\epsilon_a}} K\left(\frac{\epsilon_b + \eta}{\epsilon_a}\right) & -\epsilon_b < \eta < \epsilon_a - \epsilon_b \\ \sqrt{\frac{1}{\epsilon_b + \eta}} K\left(\frac{\epsilon_a}{\epsilon_b + \eta}\right) & \epsilon_a - \epsilon_b < \eta < 0 \\ \sqrt{\frac{1}{\epsilon_b}} K\left(\frac{\epsilon_a - \eta}{\epsilon_b}\right) & 0 < \eta < \epsilon_a \end{cases}$$

ULB

Transition Rates (3D dynamics)
P Gaspard and TG J Stat Mech P08020 (2009)

For the underlying 3D hard sphere dynamics, we obtain a simpler kernel:

$$W(\epsilon_a, \epsilon_b | \epsilon_a - \eta, \epsilon_b + \eta) =$$

$$\sqrt{\frac{\pi}{8}} \times \begin{cases} \sqrt{\frac{\epsilon_b + \eta}{\epsilon_a \epsilon_b}} & -\epsilon_b < \eta < \min(\epsilon_a - \epsilon_b, 0) \\ \frac{1}{\sqrt{\max(\epsilon_a, \epsilon_b)}} & \min(\epsilon_a - \epsilon_b, 0) < \eta < \max(\epsilon_a - \epsilon_b, 0) \\ \sqrt{\frac{\epsilon_a - \eta}{\epsilon_a \epsilon_b}} & \max(\epsilon_a - \epsilon_b, 0) < \eta < \epsilon_a \end{cases}$$

ULB

Energy Exchange Frequency

Assume a global microcanonical equilibrium at energy $E = \epsilon_1 + \cdots + \epsilon_N$. The energy exchange frequency is

$$\nu_{\mathrm{B}} = \int \mathrm{d}\epsilon \mathrm{d}\epsilon' \mathrm{d}\eta \, W(\epsilon, \epsilon' | \epsilon - \eta, \epsilon' + \eta) P_{a,b}^{(\mathrm{eq})}(\epsilon, \epsilon')$$
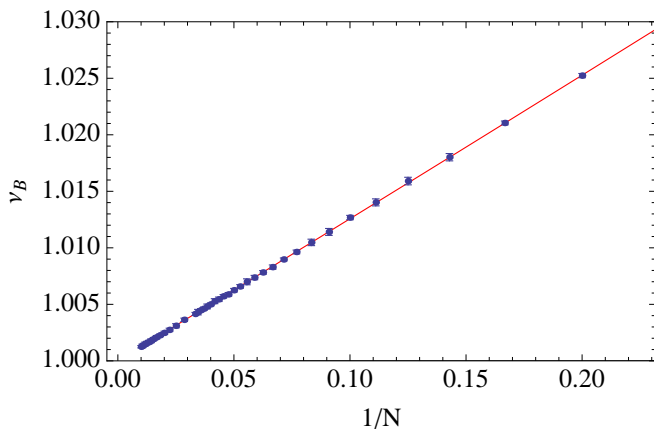

The two-particle energy distribution is

$$P_{a,b}^{(\mathrm{eq})}(\epsilon, \epsilon') = \frac{(N-1)(N-2)}{E^2} \left(1 - \frac{\epsilon + \epsilon'}{E} \right)^{N-3}$$

In the large N limit and letting $E = NT$

$$\nu_{\mathrm{B}} \simeq \sqrt{T}[1 + \mathcal{O}(N^{-1})]$$

ULB

Energy Exchange Frequency ct'd

P Gaspard and TG J Stat Mech P11021 (2008)

ULB

Energy Diffusion

Helfand moment

$$H(t) = \sum_{a=1}^{N} a\epsilon_a(t)$$

$$
\begin{aligned}
\kappa &= \lim_{N\to\infty} \frac{1}{N(E/N)^2} \lim_{n\to\infty} \left\langle \frac{1}{2\tau_n} \Delta H(\tau_n)^2 \right\rangle_{E/N} \\
&= \lim_{N\to\infty} \frac{1}{NT^2} \lim_{n\to\infty} \left[\sum_{i=1}^{n} \left\langle \frac{1}{2\tau_n} \eta(\epsilon_{k_i}, \epsilon_{k_i+1})^2 \right\rangle_T \right. \\
&\quad \left. + 2\sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \left\langle \frac{1}{2\tau_n} \eta(\epsilon_{k_i}, \epsilon_{k_i+1}) \eta(\epsilon_{k_j}, \epsilon_{k_j+1}) \right\rangle_T \right]
\end{aligned}
$$

ULB

Energy Diffusion ct'd

Only static correlations contribute (not trivial!)

$$\lim_{N\to\infty} \frac{1}{NT^2} \lim_{n\to\infty} \sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \left\langle \frac{1}{2\tau_n} \eta(\epsilon_{k_i}, \epsilon_{k_i+1}) \eta(\epsilon_{k_j}, \epsilon_{k_j+1}) \right\rangle_T = 0$$
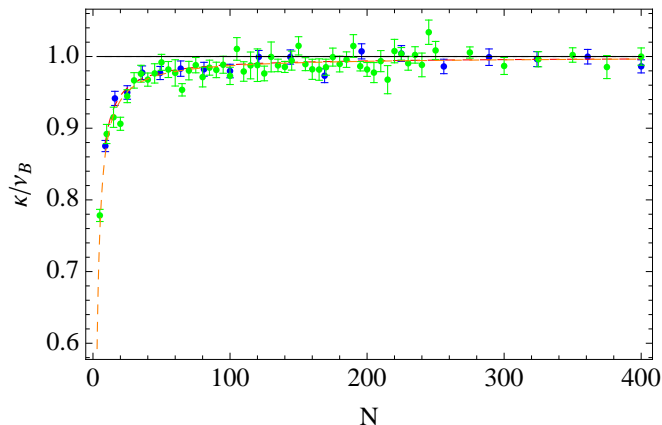

Therefore

$$\kappa = \nu_{\mathrm{B}} = \sqrt{T}$$

ULB

Energy Transport

Heat current

$$J_{a,b} = I \int \mathrm{d}\epsilon \mathrm{d}\epsilon' \mathrm{d}\eta \, \eta \, W(\epsilon, \epsilon' | \epsilon - \eta, \epsilon' + \eta) P_{a,b}^{(\mathrm{leq})}(\epsilon, \epsilon', t)$$

Local temperatures

$$T_a(t) = \int \mathrm{d}\epsilon \, \epsilon \, P_a^{(\mathrm{leq})}(\epsilon, t)$$

Fourier's law ($T_a \approx T_b$)

$$J_{a,b} = \frac{\kappa}{l}[T_a(t) - T_b(t)]$$

ULB

Non-equilibrium stationary state

Boundary conditions

$$P_{\pm N/2}(\epsilon) = \frac{1}{T_{\pm}} \exp\left(-\frac{\epsilon}{T_{\pm}}\right)$$

The one-site distribution obeys a Boltzmann-Kac equation

$$P_a(\epsilon) = \frac{1}{T_a} \exp\left(-\frac{\epsilon}{T_a}\right)$$

is a "quasi" stationary state:

$$\partial_t P_a(\epsilon, t) = \mathcal{O}(\delta T^2)$$

provided $\delta T = \frac{T_+ - T_-}{N} \ll 1$

ULB

NESS from solving the BBGKY hierarchy

Does the two-site distribution factorize?

$$P_{a,b}(\epsilon, \epsilon') \stackrel{?}{=} P_a(\epsilon)\, P_b(\epsilon')$$

No, because the current does not have the gradient form!

$$j(\epsilon, \epsilon') \neq \beta \int \mathrm{d}\epsilon''\, e^{-\beta\epsilon''} j(\epsilon, \epsilon'') - \beta \int \mathrm{d}\epsilon''\, e^{-\beta\epsilon''} j(\epsilon', \epsilon'')$$

ULB

NESS from solving the BBGKY hierarchy

The two-site distribution includes a $\mathcal{O}(\delta T)$ correction

$$P_{a,b}(\epsilon, \epsilon') = P_a(\epsilon) P_b(\epsilon') + \mathcal{O}(\delta T)$$

This correction does not affect the value of the current!

$$P_{a,b}(\epsilon, \epsilon') = P_a(\epsilon) P_b(\epsilon') + \frac{\delta\beta}{\beta} Q_{a,b}(\beta\epsilon, \beta\epsilon')$$

The second order correction correction in the cluster expansion Q is found to be a symmetric function of its arguments

ULB

Thermal Conductivity

The linear transport law yields

$$
\begin{aligned}
\frac{\kappa}{l^2} &= \frac{1}{2(T)^4} \int d\epsilon_a d\epsilon_b d\eta \; \eta(\epsilon_b - \epsilon_a) W(\epsilon_a, \epsilon_b | \epsilon_a - \eta, \epsilon_b + \eta) \\
&\quad \times \exp[-(\epsilon_a + \epsilon_b)/(T)] \\
&= \sqrt{T} \\
&= \nu_{\mathrm{B}}
\end{aligned}
$$

Thermal conductivity vs. a

Conclusions

1. Our mechanism of heat conduction proceeds in two stages : a fast local mixing stage which precedes energy exchanges leading to local thermalisation

2. The local equilibrium mechanism provides a simple accurate stochastic description of lattice billiards

3. The thermal conductivity vanishes at the critical geometry

4. The transport properties of the stochastic system can be computed assuming local thermal equilibria and reduce to a dimensional form

5. A similar two-stage mechanism is encountered in aerogels
