Dietmar Schmitz

Hannah Monyer

Simulated very fast oscillations in network of
15,000 tufted IB pyramidal cells, with g.j.
between axons

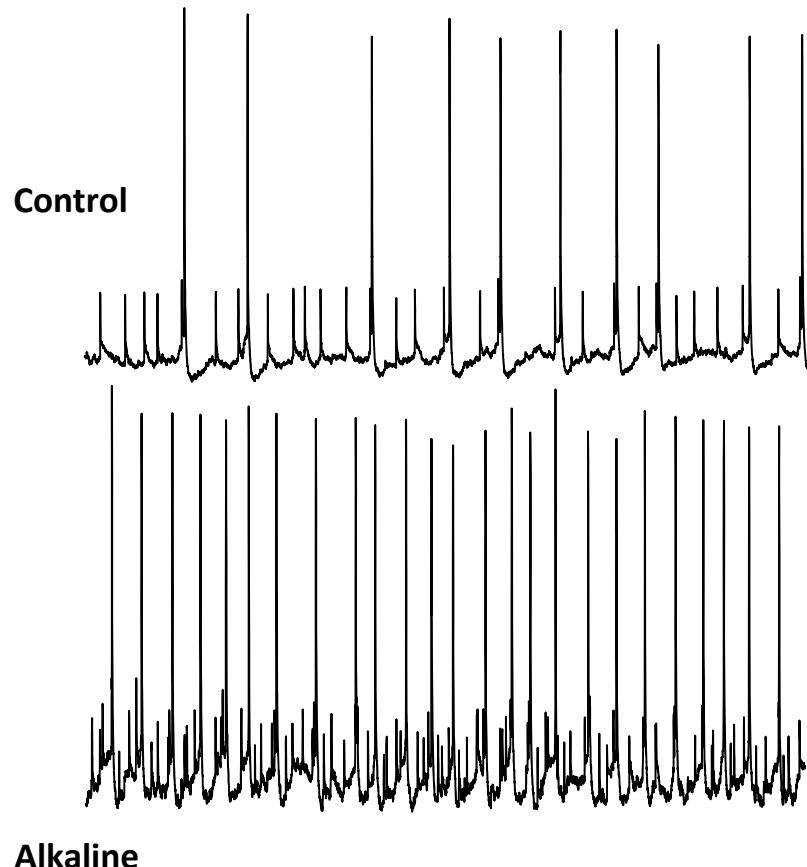

Basic model assumptions:

- 1) Each axon is electrically coupled to just a few others
- 2) Coupling is strong enough for a spike in one axon to elicit a spike in a coupled axon at short latency (< 1 ms)

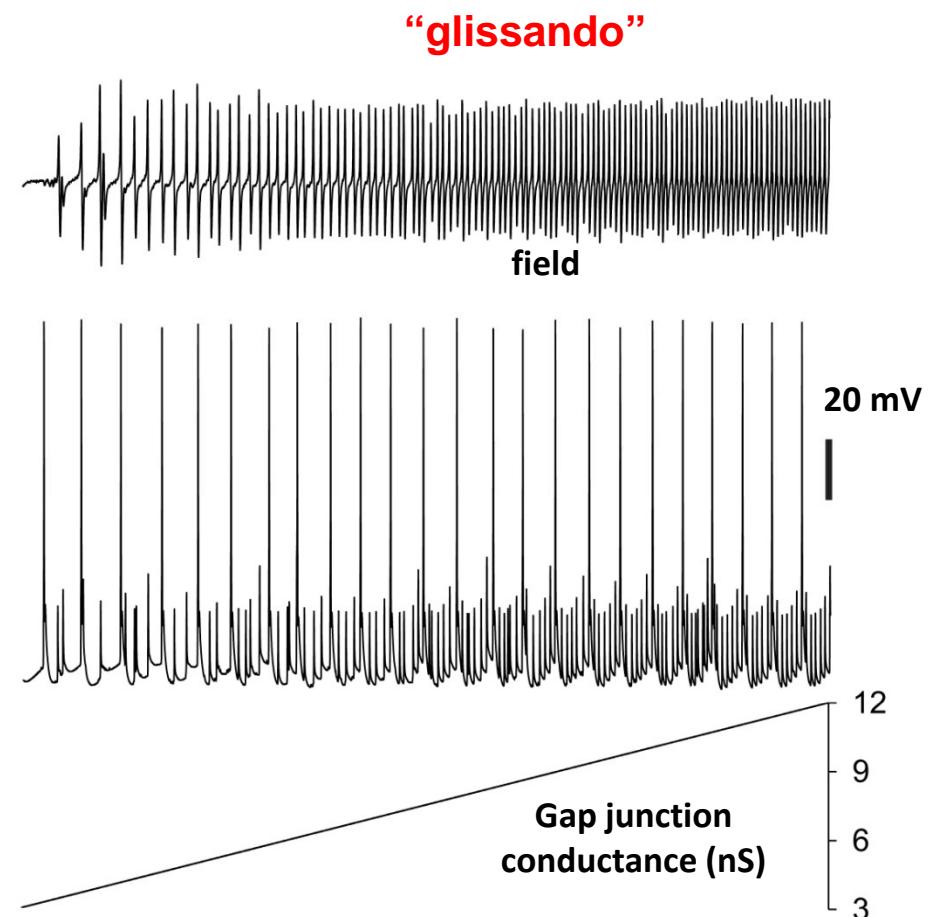

Frequency variation with coupling strength implies this can not be a system of coupled oscillators

Rat & model

R.D. Traub, R. Duncan, A.J.C. Russell,
T. Baldeweg, Y. Tu, M.O. Cunningham,
M.A. Whittington: Epilepsia, 2010

Propagation of activity in a *locally random* network of coupled, excitable elements
(c.f. Lewis & Rinzel, 2000; Traub et al., 2010)

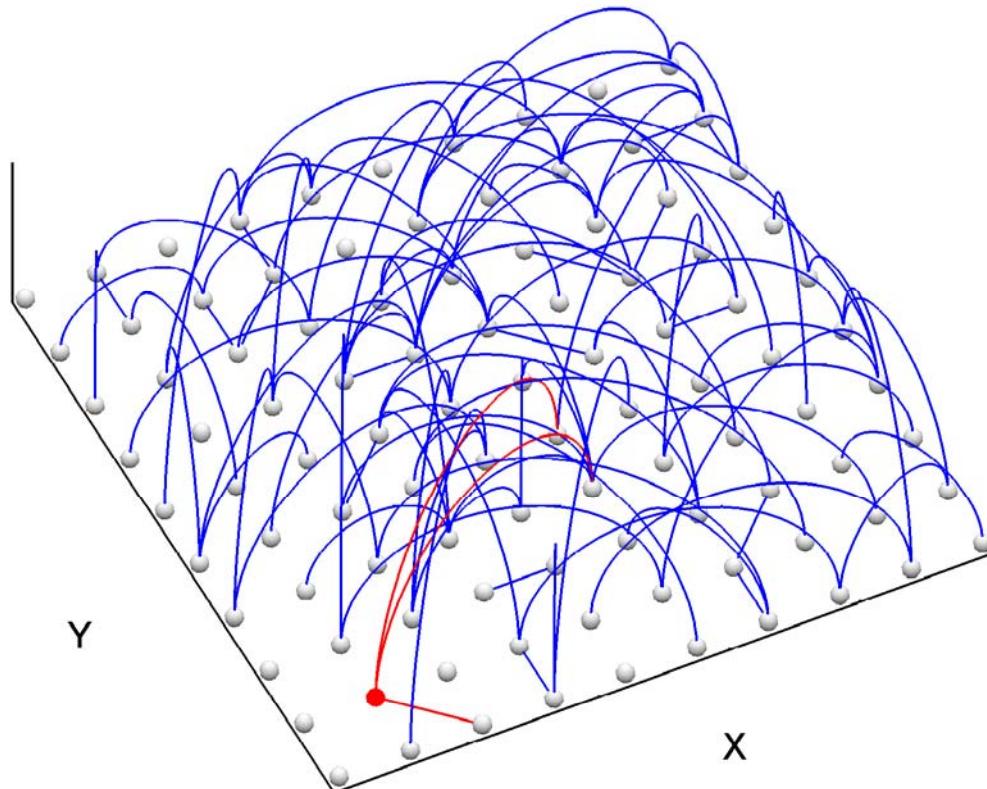

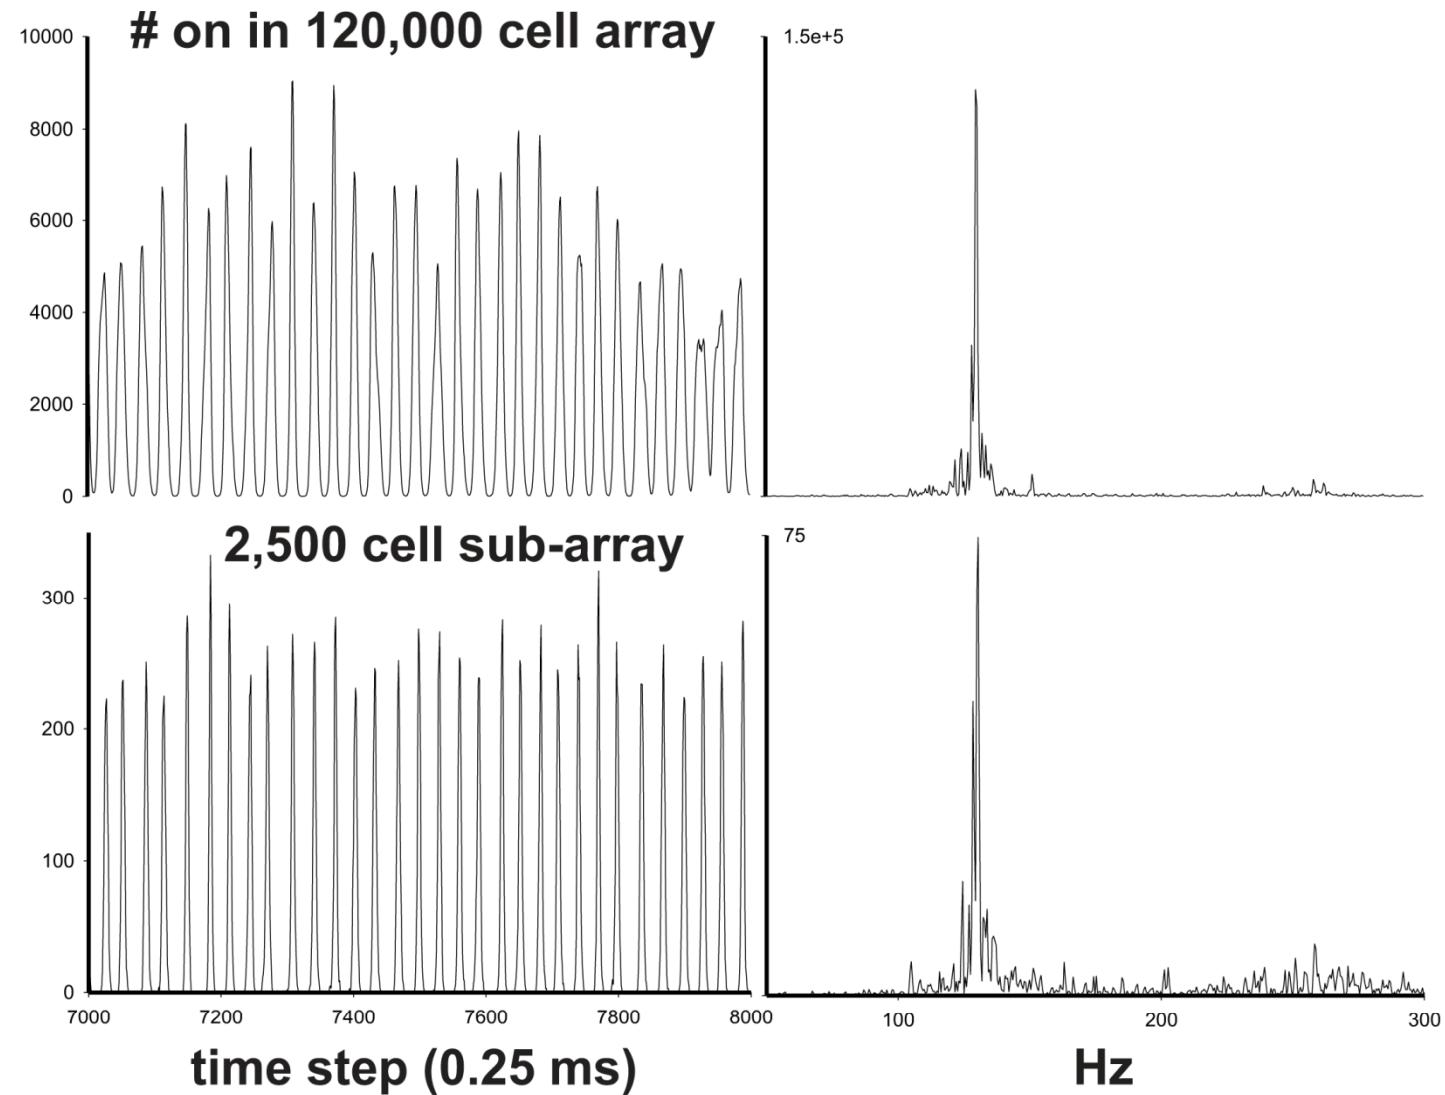

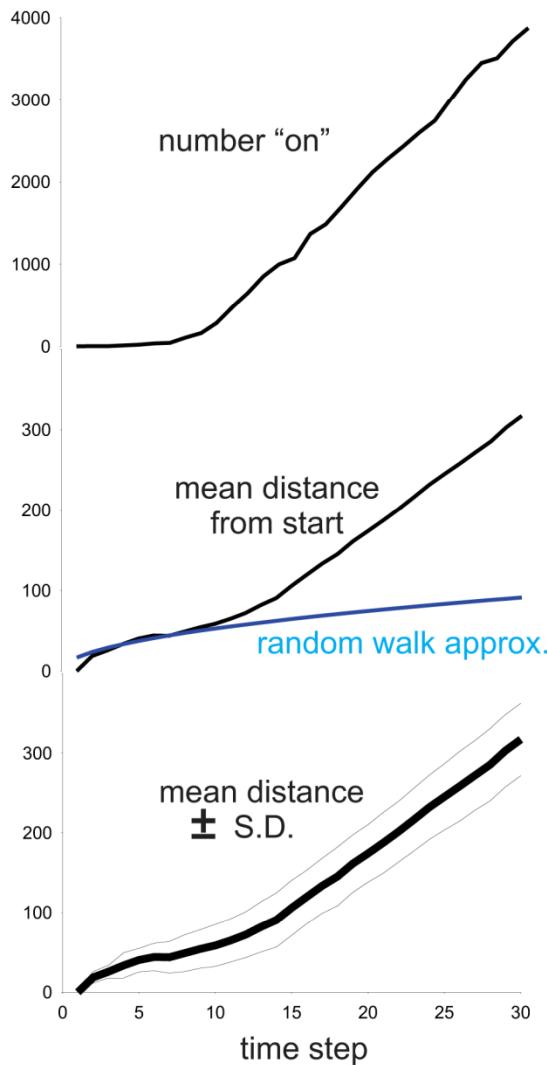

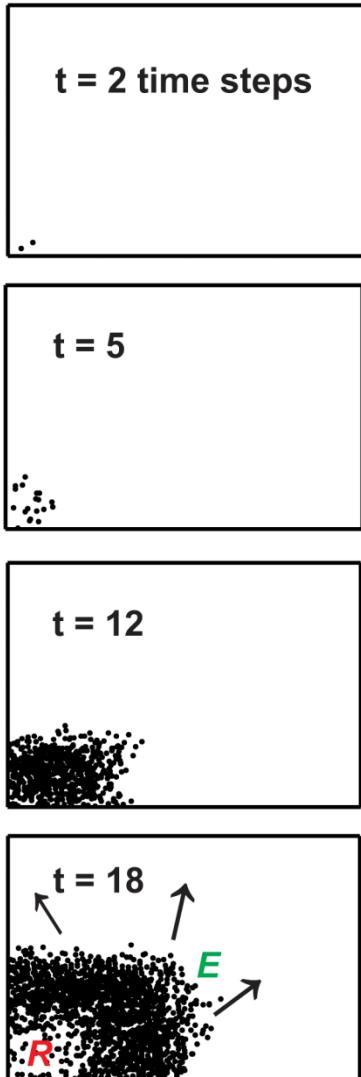

Figure: Nikita Vladimirov

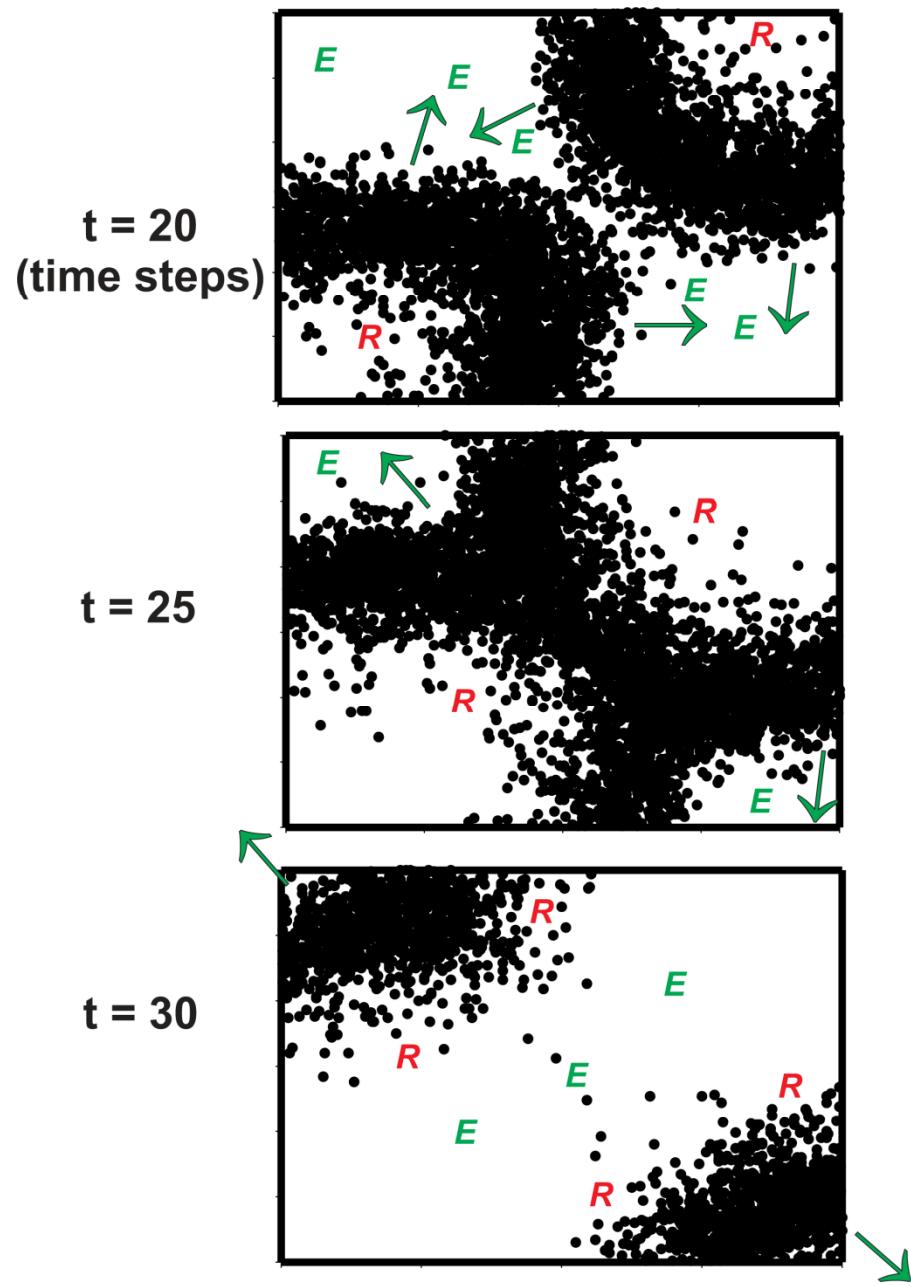

Network frequency in local-random graph is independent of spatial scale (!)

**C.A. wave propagation begins as random walk, but becomes linear.
Velocity depends on structural parameters (while period depends
on structural parameters, noise rate, and refractoriness)**

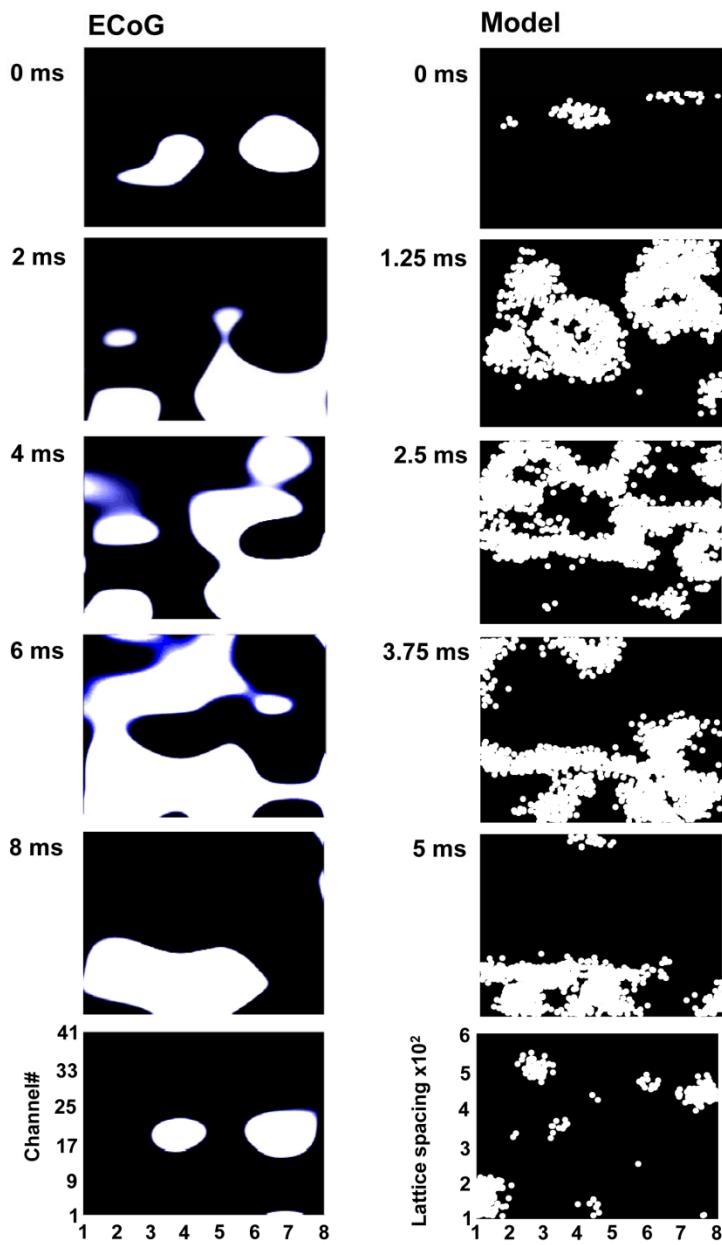

Let “k” be the index of a vertex. Then wave velocity depends on $\langle k \times k \rangle / \langle k \rangle$, independent of detailed topology.
(N. Vladimirov, R.D. Traub, Y. Tu, 2011)

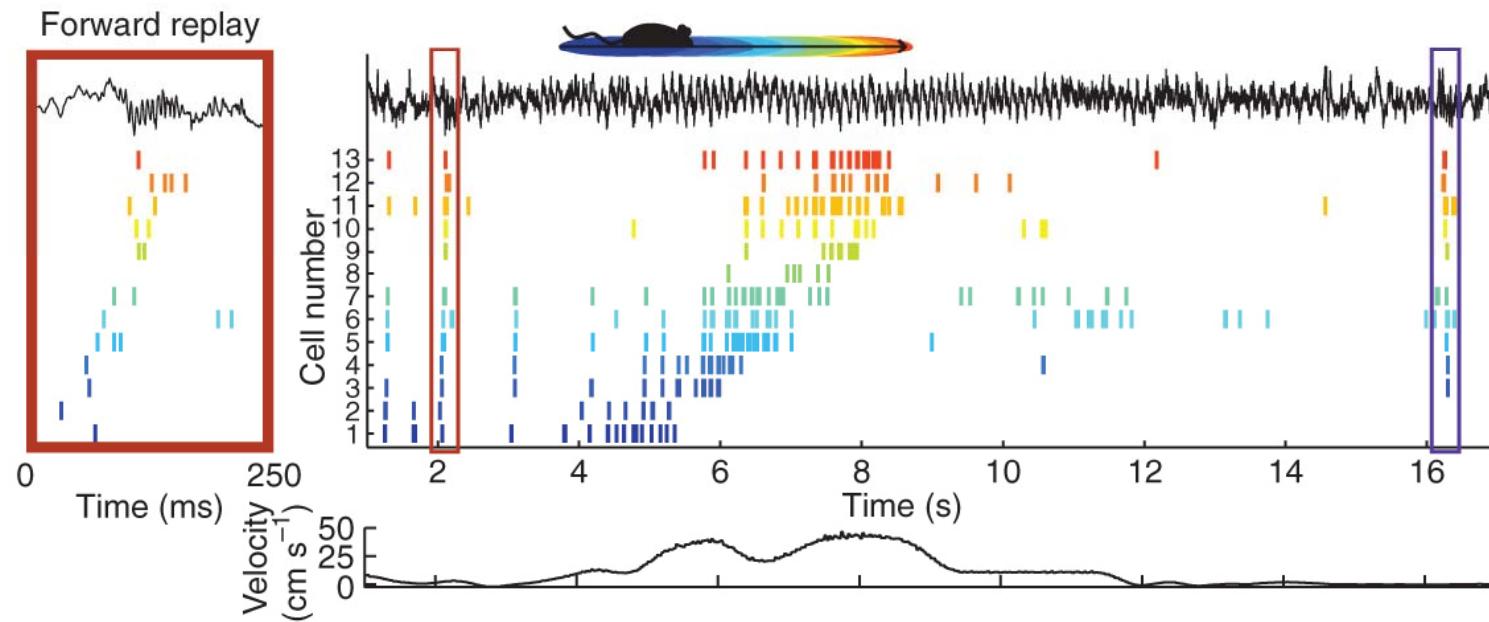

In cellular automaton model,
waves coalesce without
interpenetration or interference.

(R.D. Traub et al., Epilepsia 2010)
