

# New Examples of Noncommutative Brownian Motion

Steve Avsec

University of Ottawa

(joint work with Marius Junge and Benoit Collins)

Fields Institute, 22 July, 2013

## Definition (Collins, Junge)

Let  $\mathcal{M} = \vee_{t \geq 0} \mathcal{M}_t$  ( $\mathcal{M}_s \subset \mathcal{M}_t$  for  $s < t$ ) be a filtered finite von Neumann algebra.  $b_t$  is a Brownian motion if

- 1  $b_t$  is self-adjoint.
- 2  $b_t \in \bigcap_{1 \leq p < \infty} L^p(\mathcal{M}, \tau) := \mathcal{M}^\infty$ . (where  $\|x\|_p := \tau((x^*x)^{\frac{p}{2}})^{\frac{1}{p}}$ .)
- 3  $t \rightarrow b_t$  is continuous in  $\mathcal{M}^\infty$  with respect to the natural topology induced from the  $L^p$ -norms.
- 4  $b_t$  and  $b_t^2 - t$  are martingales. ( $E_s(b_t) = b_s$  for  $s < t$ .)
- 5  $\|b_t - b_s\|_4 \leq C|t - s|^{\frac{1}{2}}$ .
- 6 Let  $(I_k)$  be a collection of disjoint intervals such that  $|I_k| = |I_j|$  for all  $k, j$ . Let  $b_{I_k} := b_{s_k} - b_{r_k}$  where  $I_k = [r_k, s_k)$ . The  $(b_{I_k})$  are exchangeable, i.e. the sequences  $(b_{I_1}, \dots, b_{I_n})$  and  $(b_{I_{\sigma(1)}}, \dots, b_{I_{\sigma(n)}})$  are equal in distribution.

## Deformed Fock Spaces

Let  $\varphi : S_\infty \rightarrow \mathbb{R}$  be a positive definite function, and  $H$  be a real Hilbert space.

Define  $F_\varphi(H) = \bigoplus_{n \geq 0} H_{\mathbb{C}}^{\otimes n}$  to be the Fock space with the deformed inner product

$$\langle h_1 \otimes \cdots \otimes h_m, k_1 \otimes \cdots \otimes k_n \rangle = \delta_{mn} \sum_{\sigma \in S_n} \varphi(\sigma) \prod_{j=1}^n \langle h_j, k_{\sigma(j)} \rangle$$

Let  $l_\varphi(h)$  denote the left creation operator, (Toeplitz-type operator) and define

$$s_\varphi(h) = l_\varphi(h) + l_\varphi(h)^*$$

Let

$$\omega_\varphi(x) = \langle \Omega, x\Omega \rangle$$

where  $\Omega$  is the vacuum vector.

# Traciality

A straightforward calculation shows that

$$\omega(s(h_1) \dots s(h_m)) = \sum_{\nu \in P_2(m)} \psi(\nu) \prod_{\{i,j\} \in \nu} \langle h_i, h_j \rangle.$$

Let  $e_1, e_2, e_3, e_4$  be orthonormal vectors and  $s(e_j) = s_j$ .

$$\omega(s_4 s_3 s_2 s_1 s_3 s_4 s_2 s_1) = \langle e_1 \otimes e_2 \otimes e_3 \otimes e_4, e_3 \otimes e_4 \otimes e_2 \otimes e_1 \rangle = \varphi(1423)$$

Figure:  $\sigma = (1432)$

## Rotated Once

$$\omega(s_1 s_4 s_3 s_2 s_1 s_3 s_4 s_2) = \langle e_2 \otimes e_3 \otimes e_4 \otimes e_1, e_1 \otimes e_3 \otimes e_4 \otimes e_2 \rangle = (14)$$

Figure:  $\sigma = (14)$

# Rotated Again

$$\omega(s_2 s_1 s_4 s_3 s_2 s_1 s_3 s_4) = \langle e_3 \otimes e_4 \otimes e_1 \otimes e_2, e_2 \otimes e_1 \otimes e_3 \otimes e_4 \rangle = \varphi(1324)$$

Figure:  $\sigma = (1324)$

# Traciality Conditions

Notice that

$$(1423) = (1432)(243) \text{ and } (14) = (1234)(132)$$

and that

$$(14) = (1432)(234) \text{ and } (1324) = (1234)(123)$$

So the conditions we need are

$$\varphi(\rho_n \iota_1(\sigma)) = \varphi(\rho_n^{-1} \iota_2(\sigma)) \quad (1)$$

$$\varphi(\iota_1(\sigma)) = \varphi(\iota_2(\sigma)) \quad (2)$$

where  $\rho_{n+1} = (1, 2, \dots, n+1)$ ,  $\iota_1 : S_n \hookrightarrow S_{n+1}$  is the inclusion which stabilizes the last element, and  $\iota_2$  stabilizes the first.

Examples:  $\varphi(\sigma) = q^{\iota(\sigma)}$  for  $-1 \leq q \leq 1$  (Bożejko-Speicher 1991),  
 $\varphi(\sigma) = q^{n-B(\sigma)}$  for  $0 \leq q \leq 0$  (Bożejko-Speicher 1996).

# A Theorem

## Theorem (A.-Junge)

- ① *Let  $H = L^2([0, \infty), \mathbb{R})$ .  $b_t := s_\varphi(\chi_{[0,t]})$  is an exchangeable brownian motion if  $\varphi$  satisfies 1 and 2.*
- ② *Let  $(b_t)$  be an exchangeable noncommutative brownian motion. There exists a positive definite function on  $\varphi_b : S_\infty \rightarrow \mathbb{R}$  which satisfies 1 and 2 such that*

$$\tau(b_{I_n} \dots b_{I_1} b_{I_{\sigma(1)}} \dots b_{I_{\sigma(n)}}) = \varphi(\sigma)$$

**Note:** Since the real-valued positive definite functions which satisfy 1 and 2 are closed under pointwise multiplication and convex combinations, we can construct new Brownian motions from old ones using these operations.

## Why isn't this everything?

Let

$$B_t = (b_{ij}(t))_{1 \leq i, j \leq N}$$

where  $b_{ij}(t)$  are independent complex-valued brownian motions for  $i \leq j$  and  $b_{ij} = \bar{b}_{ji}$  for  $i > j$ .

In this case,  $\psi(\nu) = N^{-g(\nu)}$  where  $g$  denotes the *genus* number of  $\nu$ .

Let  $\varphi$  denote the restriction of  $\psi$  to permutations.

$\varphi$  is positive definite and satisfies 1 and 2, so we may apply our theorem to obtain a brownian motion  $b'_t$ . However,  $b'_t$  is not the same brownian motion as  $B_t$ !

## Why isn't this everything?

## Another Example (due to M. Guta)

Let  $\psi_1, \dots, \psi_m$  be functions on pair partitions which arise as moments of brownian motions  $b_t^1, \dots, b_t^m$ .

For a pair partition  $\nu \in P_2(2n)$ , define

$$\psi_1 *_q \psi_2 *_q \cdots *_q \psi_n(\nu) = m^{-n} \sum_{c: \nu \rightarrow \{1, \dots, m\}} q^{\iota(c, \nu)} \prod_j \psi_j(c^{-1}(j))$$

where  $\iota(c, \nu) = \frac{1}{2} | \{ (a, b) \mid a \text{ crosses } b, c(a) \neq c(b) \} |$ .

For example,  $\psi_{q_1} *_q \psi_{q_2}$  gives a brownian motion which does not come from the “naïve” construction.

## Another Example (due to M. Guta)

Let  $\psi_1, \dots, \psi_m$  be functions on pair partitions which arise as moments of brownian motions  $b_t^1, \dots, b_t^m$ .

For a pair partition  $\nu \in P_2(2n)$ , define

$$\psi_1 *_q \psi_2 *_q \cdots *_q \psi_n(\nu) = m^{-n} \sum_{c: \nu \rightarrow \{1, \dots, m\}} q^{\iota(c, \nu)} \prod_j \psi_j(c^{-1}(j))$$

where  $\iota(c, \nu) = \frac{1}{2} |(a, b) | a \text{ crosses } b, c(a) \neq c(b) \}|$ .

For example,  $\psi_{q_1} *_q \psi_{q_2}$  gives a brownian motion which does not come from the “naïve” construction.

## Another Example (due to M. Guta)

Let  $\psi_1, \dots, \psi_m$  be functions on pair partitions which arise as moments of brownian motions  $b_t^1, \dots, b_t^m$ .

For a pair partition  $\nu \in P_2(2n)$ , define

$$\psi_1 *_q \psi_2 *_q \cdots *_q \psi_n(\nu) = m^{-n} \sum_{c: \nu \rightarrow \{1, \dots, m\}} q^{\iota(c, \nu)} \prod_j \psi_j(c^{-1}(j))$$

where  $\iota(c, \nu) = \frac{1}{2} | \{ (a, b) \mid a \text{ crosses } b, c(a) \neq c(b) \} |$ .

For example,  $\psi_{q_1} *_q \psi_{q_2}$  gives a brownian motion which does not come from the “naïve” construction.

Thank You!
