MLDS in RKHS

#### Outline

- Elements of Learning Theory and Function Approximation in RKHSs
- Probability Measures in RKHSs and the Maximum Mean Discrepancy
- Kernel Flows for Learning Chaotic Dynamical Systems: Parametric Kernel Flows, NonParametric Kernel Flows, Irregular Time-Series, Partial Observations, Sparse Kernel Flows.
- Detection of Critical Transitions for some Slow-Fast SDEs
- Approximation of Center Manifolds in RKHSs
- Construction of Lyapunov Functions in RKHSs
- Review of Some Concepts of Linear Control Systems
- Approximation of Nonlinear Control Systems in RKHSs
- Review of Some Concepts of Linear SDEs
- Learning SDEs

• Estimation of the Stationary Solution of the Fokker-Planck Equation of nonlinear SDEs

• We assume that there is a  $\phi : \mathbb{R}^n \to \mathcal{H}; x \mapsto z$  where  $\mathcal{H}$  is an RKHS such that we can perform an analysis (in general, but not necessarily, a linear analysis) in  $\mathcal{H}$  then come back to  $\mathbb{R}^n$ .

• The transformation  $\phi$  is obtained from the kernel that defines the RKHS (in general, it is not necessary to explicitly find  $\phi$ ). In practice, we will use  $\phi(x) = [\phi_1(x) \cdots \phi_N(x)]^T$  with

$$\phi_i(x) = K(x, x(t_i))$$

where K is a reproducing kernel and  $x(t_i)$  are measurements at time  $t_i$ ,  $i = 1, \dots, N$  and  $N \gg n$ .

• Measurements/Data are used to construct the Hilbert Space where computations become "simpler".

- Historical Context: Appeared in the 1930s as an answer to the question: when is it possible to embed a metric space into a Hilbert space ? (Schoenberg, 1937)
- Answer: If the metric satisfies certain conditions, it is possible to embed a metric space into a special type of Hilbert spaces called RKHSs.
- Properties of RKHSs have been further studied in the 1950s and later (Aronszajn, 1950; Schwartz, 1964 etc.)

- Definition: A Hilbert Space is an inner product space that is complete and separable with respect to the norm defined by the inner product.
  Definition: For a compact X ⊆ ℝ<sup>d</sup>, and a Hilbert space H of functions f : X → ℝ, we say that H is a RKHS if there exists k : X × X → ℝ such that
  - i. k has the reproducing property, i.e.  $\forall f \in \mathcal{H}, f(x) = \langle f(\cdot), k(\cdot, x) \rangle$  (k is called a reproducing kernel).
  - ii. k spans  $\mathcal{H}$ , i.e.  $\mathcal{H} = \overline{\text{span}\{k(x, \cdot) | x \in \mathcal{X}\}}$ .

• Definition: A Reproducing Kernel Hilbert Space (RKHS) is a Hilbert space *H* with a reproducing kernel whose span is dense in H. Equivalently, a RKHS is a Hilbert space of functions where all evaluation functionals are bounded and linear.

### Reproducing Kernel Hilbert Spaces

The important properties of reproducing kernels are

- The RKHS is unique.
- $\forall x, y \in \mathcal{X}$ , K(x, y) = K(y, x) (symmetry).
- $\sum_{i,j=1}^{m} \alpha_i \alpha_j K(x_i, x_j) \ge 0$  for  $\alpha_i \in \mathbb{R}$  and  $x_i \in \mathcal{X}$  (positive definitness).

•  $\langle K(x, \cdot), K(y, \cdot) \rangle_{\mathcal{H}} = K(x, y)$ . Using this property, one can immediately get the canonical feature map (Aronszajn's feature map):  $\Phi_c(x) = K(x, \cdot)$ .

• A Mercer kernel is a continuous positive definite kernel.

• The fact that Mercer kernels are positive definite and symmetric reminds us of similar properties of Gramians and covariance matrices. This is an essential fact that we are going to use in the following.

• Examples of kernels:  $k(x, x') = \langle x, x' \rangle^d$ ,  $k(x, x') = \exp\left(-\frac{||x-x'||_2^2}{2\sigma^2}\right)$ ,  $k(x, x') = \tanh(\kappa \langle x, x' \rangle + \theta)$ .

> < 同 > < 回 > < 回 >

#### Reproducing Kernel Hilbert Spaces

• Mercer Theorem: Let  $(\mathcal{X}, \mu)$  be a finite-measure space, and suppose  $k \in L_{\infty}(\mathcal{X}^2)$  is a symmetric real-valued function such that the integral operator

$$egin{array}{rcl} L_k: L_2(\mathcal{X}) & o & L_2(\mathcal{X}) \ & f & \mapsto & (L_k f)(x) = \int_{\mathcal{X}} k(x,x') f(x') d\mu(x') \end{array}$$

is positive definite; that is, for all  $f \in L_2(\mathcal{X})$ , we have  $\int_{\mathcal{X}^2} k(x, x') f(x) f(x') d\mu(x) d\mu(x') \ge 0$ . Let  $\Psi_j \in L_2(\mathcal{X})$  be the normalized orthogonal eigenfunctions of  $L_k$ associated with the eigenvalues  $\lambda_j > 0$ , sorted in non-increasing order. Then

i.  $(\lambda_j)_j \in \ell_1$ ,

ii.  $k(x, x') = \sum_{j=1}^{N_{\mathcal{X}}} \lambda_j \Psi_j(x) \Psi_j(x')$  holds for almost all (x, x'). Either  $N_{\mathcal{X}} \in \mathbb{N}$ , or  $N_{\mathcal{X}} = \infty$ ; in the latter case, the series converges absolutely and uniformly for almost all  $(x, x')_{\mathbb{T}} \times \mathbb{R}$ .

Boumediene Hamzi

• Proposition (Mercer Kernel Map): If k is a Mercer kernel, it is possible to construct a mapping  $\Phi$  into a space where k acts as a dot product,

 $\langle \Phi(x), \Phi(x') \rangle = k(x, x'),$ 

for almost all  $x, x' \in \mathcal{X}$ .

• From Mercer's theorem  $\Phi: X \to \ell^2$  is

$$\Phi_i(x) = \sqrt{\lambda_i} \Psi_i(x).$$

- $\Phi$  is not unique and depends on the measure  $\mu$ .
- $\Phi$  is difficult to compute in general.

### Reproducing Kernel Hilbert Spaces

- It is unnecessary to invoke Mercer's theorem just for discussing feature maps/spaces.
- Example of non-Mercer feature maps using  $\Phi(x) = K(x, \cdot)$ 
  - For a polynomial kernel  $K(x,t) = \langle x,t \rangle^2$ ,

$$\Phi: (x_1, x_2) \to (x_1^2, x_2^2, \sqrt{2}x_1x_2) \in \mathbb{R}^3.$$

• For a Gaussian kernel  $K(x,t) = e^{-\frac{||x-t||^2}{\sigma^2}}$ ,

$$\Phi: x \to e^{-\frac{||x||^2}{\sigma^2}} \left( \sqrt{\frac{(2/\sigma^2)^k C_{\alpha}^k}{k!}} x^{\alpha} \right) \Big|_{|\alpha|=k,k=0}^{\infty} \in \ell^2.$$

• Mercer theorem is, however, fundamental to find error estimates and study the smoothing properties of kernels.

Boumediene Hamzi

MLDS in RKHS

• RKHS play an important role in learning theory whose objective is to find an unknown function  $f: X \to Y$  from random samples  $(x_i, y_i)|_{i=1}^m$ . • For instance, assume that the random probability measure that governs the random samples is  $\rho$  and is defined on  $Z := X \times Y$ . Let X be a compact subset of  $\mathbb{R}^n$  and  $Y = \mathbb{R}$ . If we define the least square error of f as  $\mathcal{E} = \int_{X \times Y} (f(x) - y)^2 d\rho$ , then the function that minimizes the error is the regression function  $f_{\rho}$  defined as

$$f_{\rho}(x) = \int_{\mathbb{R}} y d\rho(y|x), \quad x \in X,$$

where  $\rho(y|x)$  is the conditional probability measure on  $\mathbb{R}$ .

• Since  $\rho$  is unknown, neither  $f_{\rho}$  nor  $\mathcal{E}$  is computable. We only have the samples  $\mathbf{s} := (x_i, y_i)|_{i=1}^m$ . The error  $\mathcal{E}$  is approximated by the empirical error  $\mathcal{E}_{\mathbf{s}}(f)$  by

$$\mathcal{E}_{\mathbf{s}}(f) = \frac{1}{m} \sum_{i=1}^{m} (f(x_i) - y_i)^2 + \lambda ||f||_{\mathcal{H}}^2,$$

for  $\lambda \geq 0, \, \lambda$  plays the role of a regularization parameter.

• In learning theory, the minimization is taken over functions from a hypothesis space often taken to be a ball of a RKHS  $\mathcal{H}_K$  associated to a kernel K, and the function  $f_s$  that minimizes the empirical error  $\mathcal{E}_s$  is

$$f_{\mathbf{s}}(x) = \sum_{j=1}^{m} c_j K(x, x_j) = \sum_{j=1}^{m} c_j \phi_j(x),$$

where the coefficients  $(c_j)_{j=1}^m$  are obtained by solving the linear system

$$\lambda m c_i + \sum_{j=1}^m K(x_i, x_j) c_j = y_i, \quad i = 1, \cdots m,$$

and  $f_s$  is taken as an approximation of the regression function  $f_{\rho}$ . • We call *learning* the process of approximating the unknown function f from random samples on Z.

Boumediene Hamzi

#### RKHS in Approximation Theory (aka Learning Theory)

• Now, suppose we are given a set of points  $\mathbf{x} = (x_1, \cdots, x_m)$  sampled i.i.d. according to  $\rho$ . Many problems in Learning Theory deal with the empirical kernel matrix  $\mathbb{K} \in \mathbb{R}^{m \times m}$  whose entries are

$$\mathbb{K}_{i,j} = \frac{1}{m} K(x_i, x_j).$$

• The restriction operator  $\mathcal{R}_{\mathbf{x}} : \mathcal{H}_K \to \mathbb{R}^m$  with a discrete subset  $(\mathbf{x}_i)|_{i=1}^m \in X$  is defined as

$$\mathcal{R}_{\mathbf{x}}f = (f(x_i))_{i=1}^m$$

The adjoint of the restriction operator,  $\mathcal{R}^*_{\mathbf{x}} : \mathbb{R}^m \to \mathcal{H}_K$  is given by

$$\mathcal{R}_{\mathbf{x}}^* c = \sum_{i=1}^m c_i K(x, x_i), \quad c \in \mathbb{R}^m$$

Boumediene Hamzi

#### **RKHS** in Change Point Detection

- We will consider a sequence of samples x<sub>1</sub>, x<sub>2</sub>, · · · , x<sub>n</sub> from a domain X.
  We are interested in detecting a possible change-point τ, such that
- before  $\tau$ , the samples  $x_i \sim P$  i.i.d for  $i \leq \tau$ , where P is the so-called background distribution, and after the change-point, the samples  $x_i \sim Q$  i.i.d for  $i \geq \tau + 1$ , where Q is a post-change distribution.
- We map the dataset in an RKHS  $\mathcal{H}$  then compute a measure of discrepancy  $\Delta_n$ .
- $\Delta_n$  is small if P = Q and large if P and Q are far apart.
- We will use the maximum mean discrepancy (MMD)

$$\mathsf{MMD}[\mathcal{H}, P, Q] := \sup_{f \in \mathcal{H}, ||f|| \le 1} \{ \mathbb{E}_x[f(x)] - \mathbb{E}_y[f(y)] \},\$$

as a measure of heteregoneity.

• Let  $\mathcal{H}$  be an RKHS on the separable metric space  $\mathcal{X}$ , with a continuous feature mapping  $\phi : \mathcal{X} \to \mathcal{H}$ . Assume that k is bounded, i.e.  $\sup_{\mathcal{X}} k(x, x) < \infty$ .

• Let  $\mathcal{P}$  be the set of Borel probability measures on  $\mathcal{X}$ . We define the mapping to  $\mathcal{H}$  of  $P \in \mathcal{P}$  as the expectation of  $\phi(x)$  with respect to P, i.e.

$$\begin{array}{rcl} \mu_P: \mathcal{P} & \to & \mathcal{H} \\ P & \mapsto & \int_{\mathcal{X}} \phi(x) dP(x) =: \mu_k(P) \quad \text{(kernel mean embedding of P)} \end{array}$$

• The maximum mean discrepancy (MMD) between two probability measures P and Q is defined as the distance between two such mappings

$$MMD(P,Q) = ||\mu_k(P) - \mu_k(Q)||_{\mathcal{H}_k}$$

• The maximum mean discrepancy (MMD) is defined as (Gretton et al., 2007)

 $\mathsf{MMD}(P,Q) := ||\mu_P - \mu_Q||_{\mathcal{H}},$ 

 $= \left(\mathbb{E}_{x,x'}(k(x,x')) + \mathbb{E}_{y,y'}(k(y,y')) - 2\mathbb{E}_{x,y}(k(x,y))\right)^{\frac{1}{2}}$ where x and x' are independent random variables drawn according to P, y

and y' are independent random variables drawn according to Q, and x is independent of y.

• This quantity is a pseudo-metric on distributions, i.e. it satisfies all the qualities of a metric except MMD(P,Q) = 0 iff P = Q.

• For the MMD to be a metric, it is sufficient that the kernel is characteristic, i.e. the map  $\mu_P : \mathcal{P} \to \mathcal{H}$  is injective. This is satisfied by the Gaussian kernel (both on compact domains and on  $\mathbb{R}^d$ ) for example.

#### Probability Measures in RKHSes

• RKHS embedding:

$$P \to \mu_k(P) = \mathbb{E}_{X \sim P} k(\cdot, X) \in \mathcal{H}_k$$

$$P \to [\mathbb{E}\varphi_1(X), \cdots, \mathbb{E}\varphi_s(X)] \in \mathbb{R}^s$$

 Maximum Mean Discrepancy (MMD) [Borgwardt et al, 2006; Gretton et al, 2007] between P and Q:

イロト イポト イヨト イヨト

 $\bullet$  For characteristic kernels, the MMD metrizes the weak-  $\star$  topology on probability measures

 $\mathsf{MMD}_k(P_n,P)\to 0\Leftrightarrow P_n\rightsquigarrow P$ 

• For characteristic kernels: convergence in distribution iff convergence in MMD.

• It is an Integral Probability Metric that can be computed directly from data without having to estimate the density as an intermediate step.

• Given two i.i.d samples  $(x_1, \cdots, x_m)$  from P and  $(y_1, \cdots, y_m)$  from Q, an unbiased estimate of the MMD is

$$\mathsf{MMD}_{u}^{2} := \frac{1}{m(m-1)} \sum_{i \neq j}^{m} [k(x_{i}, x_{j}) + k(y_{i}, y_{j}) - k(x_{i}, y_{j}) - k(x_{j}, y_{i})]$$

Boumediene Hamzi

MLDS in RKHS

ロ ▶ ◀ ⓓ ▶ ◀ 重 ▶ ◀ 重 ▶ 重 ዏ ៚ 3rd Symp. on MLDS, Fields Inst., 09/2022

• Problem **P** : Given input/output data  $(x_1, y_1), \dots, (x_N, y_N) \in \mathcal{X} \times \mathbb{R}$ , recover an unknown function  $u^*$  mapping  $\mathcal{X}$  to  $\mathbb{R}$  such that  $u^*(x_i) = y_i$ for  $i \in \{1, ..., N\}$ .

• In the setting of optimal recovery, Problem **P** can be turned into a well posed problem by restricting candidates for u to belong to a Banach space of functions  $\mathcal{B}$  endowed with a norm defined as

$$||u||^2 = \sup_{\phi \in \mathcal{B}^*} \frac{(\int \phi(x)u(x)dx)^2}{(\int \phi(x)K(x,y)\phi(y)dxdy)}$$

and identifying the optimal recovery as the minimizer of the relative error

$$\mathsf{min}_v\mathsf{max}_u\frac{||u-v||^2}{||u||^2},$$

where the max is taken over  $u \in \mathcal{B}$  and the min is taken over candidates in  $v \in \mathcal{B}$  such that  $v(x_i) = u(x_i) = y_i$ .

• The method of KFs is based on the premise that a kernel is good if there is no significant loss in accuracy in the prediction error if the number of data points is halved. This led to the introduction of

$$\rho = \frac{||v^* - v^s||^2}{||v^*||^2}$$

which is the relative error between  $v^*$ , the optimal recovery of  $u^*$  based on the full dataset  $X = \{(x_1, y_1), \ldots, (x_N, y_N)\}$ , and  $v^s$  the optimal recovery of both  $u^*$  and  $v^*$  based on half of the dataset  $X^s = \{(x_i, y_i) \mid i \in S\}$ (Card(S) = N/2) which admits the representation

$$v^s = (y^s)^T A^s K(x^s, \cdot)$$

with  $y^s = \{y_i \mid i \in S\}$ ,  $x^s = \{x_i \mid i \in S\}$ ,  $A^s = (\Theta^s)^{-1}$ ,  $\Theta^s_{i,j} = K(x^s_i, x^s_j)$ .

Given a family of kernels  $K_{\theta}(x, x')$  parameterized by  $\theta$ , the KF algorithm can then be described as follows :

- 1. Select random subvectors  $X^b$  and  $Y^b$  of X and Y (through uniform sampling without replacement in the index set  $\{1, \ldots, N\}$ )
- 2. Select random subvectors  $X^c$  and  $Y^c$  of  $X^b$  and  $Y^b$  (by selecting, at random, uniformly and without replacement, half of the indices defining  $X^b$ )
- 3. Let

$$\rho(\theta, X^b, Y^b, X^c, Y^c) := 1 - \frac{Y^{c,T} K_{\theta}(X^c, X^c)^{-1} Y_c}{Y^{f,T} K_{\theta}(X^b, X^b)^{-1} Y^b},$$

be the squared relative error (in the RKHS norm  $\|\cdot\|_{K_{\theta}}$  defined by  $K_{\theta}$ ) between the interpolants  $u^{b}$  and  $u^{c}$  obtained from the two nested subsets of the dataset and the kernel  $K_{\theta}$ 

- 4. Evolve  $\theta$  in the gradient descent direction of  $\rho$ , i.e.  $\theta \leftarrow \theta \delta \nabla_{\theta} \rho$
- 5. Repeat.

• Let  $x_1, \ldots, x_k, \ldots$  be a time series in  $\mathbb{R}^d$ . Our goal is to forecast  $x_{n+1}$  given the observation of  $x_1, \ldots, x_n$ .

• We work under the assumption that this time series can be approximated by a solution of a dynamical system of the form

$$z_{k+1} = f^{\dagger}(z_k, \dots, z_{k-\tau^{\dagger}+1}),$$

where  $\tau^{\dagger} \in \mathbb{N}^{*}$  and  $f^{\dagger}$  may be unknown.

• Given  $\tau \in \mathbb{N}^*$ , the approximation of the dynamical can then be recast as that of interpolating  $f^{\dagger}$  from pointwise measurements

$$f^{\dagger}(X_k) = Y_k$$
 for  $k = 1, \dots, N$ 

with  $X_k := (x_{k+\tau-1}, ..., x_k)$ ,  $Y_k := x_{k+\tau}$  and  $N = n - \tau$ .

• Given a reproducing kernel Hilbert space of candidates for  $f^{\dagger}$ , and using the relative error in the RKHS norm  $\|\cdot\|$  as a loss, the regression of the data  $(X_k, Y_k)$  with the kernel K associated with provides a minimax optimal approximation of  $f^{\dagger}$  in . This interpolant (in the absence of measurement noise) is

$$f(x) = K(x, X)(K(X, X))^{-1}Y$$

where  $X = (X_1, \ldots, X_N)$ ,  $Y = (Y_1, \ldots, Y_N)$ , k(X, X) for the  $N \times N$  matrix with entries  $k(X_i, X_i)$ , and k(x, X) is the N vector with entries  $k(x, X_i)$ .

• Use different variants of Kernel Flows (KF) to learn the kernel K from the data  $(X_k, Y_k)$ .

Assume the kernel K to be parameterized by  $\theta$ . To update  $\theta$  in  $K_{\theta}$ , we minimize one of the following metrics (different variants of KFs)

Metric associated to the RKHS norm

$$\rho(\theta, X^b, Y^b, X^c, Y^c) := 1 - \frac{Y^{c,T} K_{\theta}(X^c, X^c)^{-1} Y_c}{Y^{f,T} K_{\theta}(X^b, X^b)^{-1} Y^b}$$

Metric associated to Lyapunov exponents and the premise that a kernel is good if the estimate of the maximal Lyapunov exponent obtained from the kernel approximation of the dynamics does not change if half of the data is used:

$$\rho_L = |\lambda_{\max,N} - \lambda_{\max,N/2}|$$

 Metric associated to the Maximum Mean Discrepancy (MMD) and minimize

$$\rho_{\mathsf{MMD}} = \mathsf{MMD}(S_1, S_2)$$

between two different samples of the time series.

Boumediene Hamzi

• We use the kernel

$$\begin{aligned} k(x,y) &= \alpha_0 \max\{0, 1 - \frac{||x - y||_2^2|}{\sigma_0}\} + \alpha_1 e^{\frac{||x - y||_2^2}{\sigma_1^2}} + \alpha_2 e^{-\frac{||x - y||_2}{\sigma_2^2}} \\ &+ \alpha_3 e^{-\sigma_3 \sin^2(\sigma_4 \pi ||x - y||_2)} e^{-\frac{||x - y||_2^2}{\sigma_5^2}} + \alpha_4 ||x - y||_2^2 \end{aligned}$$

• Bernoulli map  $x(k+1) = 2x(k) \mod 1$

# Nonparametric Kernel Flows for Learning Chaotic Dynamical Systems

• Write  $X := (X_1, \ldots, X_N)$  and  $Y := (Y_1, \ldots, Y_N)$  for the input/output training data. Our goal is to learn a kernel of the form

$$K^{\phi}(x, x') = K(\phi(x, 1), \phi(x', 1)),$$

where K is a standard kernel and  $\phi$  maps the input space into itself.

# Nonparametric Kernel Flows for Learning Chaotic Dynamical Systems

 $\bullet$  The warping of the input space  $\phi$  satisfies the following ODE

$$\begin{cases} \dot{\phi}(x,t) = & v(\phi(x,t),t) \\ \phi(x,0) = & x \end{cases}$$

with

$$v(x,t)=\Gamma(x,q)\Gamma(q,q)^{-1}\dot{q}, \quad \text{and} \quad \dot{q}=-\nabla\big[\rho(q)\big],$$

where

- q corresponds to position variables in  $\mathcal{X}^N$  starting from  $q(0) = X = (X_1, \cdots, X_N).$
- $\Gamma$  is an operator/vector-valued kernel,  $\Gamma(q,q)$  is an  $N \times N$  matrix with entries  $\Gamma(q_i, q_j)$ .
- $\Gamma(x,q)$  is a  $1 \times N$  vector with entries  $\Gamma(x,q_i)$ .
- $\rho$  is the kernel flow loss associated with the input/output data (q, Y).
### Nonparametric Kernel Flows for Learning Chaotic Dynamical Systems

• Using an explicit Euler scheme and regularizing with a nugget  $\lambda>0$  leads to an iteration of the form

$$\phi_{n+1}(x) = \phi_n(x) + \epsilon v_n(\phi_n(x)).$$

with  $\phi_0(x) = x$ . • Writing  $X = (X_1, \ldots, X_N)$  for the training points and  $q_n := \phi_n(X) := (\phi_n(X_1), \ldots, \phi_n(X_N))$ , the discretized equations take the form

$$q_{n+1} = q_n - \epsilon \nabla \rho(q_n)$$

and

$$v_n(x) = \Gamma(x, q_n) \left( \Gamma(q_n, q_n) + \lambda I \right)^{-1} (q_{n+1} - q_n) / \epsilon$$

MLDS in RKHS

• The above approach fails to be accurate for irregularly sampled series because it discards the information contained in the  $t_k$ .

• To address this issue, we consider the model

$$x_{k+1} = f^{\dagger}(x_k, \Delta_k, \dots, x_{k-\tau^{\dagger}+1}, \Delta_{k-\tau^{\dagger}+1}),$$

which incorporates the time differences  $\Delta_k = t_{k+1} - t_k$  between observations.

• That is, we employ a time-aware time series representations by interleaving observations and time differences.

• The proposed strategy is then to construct a surrogate model by regressing  $f^{\dagger}$  from past data and a kernel  $K_{\theta}$  learned with Kernel Flows as described previously. Note that the past data takes are

$$X_k := (x_k, \Delta_k, \dots, x_{k+\tau-1}, \Delta_{k+\tau-1}), Y_k := x_{k+1} \text{ and } N = n - \tau.$$

### Kernel Flows for Learning Irregularly-Sampled Time Series

Figure: Approach with regular Kernel Flows (left), Approach with irregular Kernel Flows (right).

• Consider the dynamical system

$$x(k+1) = f(x(k)) = \begin{bmatrix} f_n(x) \\ f_m(x) \end{bmatrix}$$

where  $f \in \mathcal{C}(\mathbb{R}^n \times \mathbb{R}^m, \mathbb{R}^{n+m})$ .

• We assume that we have access to measurements from the first n components of the x-variable that we denote as  $x^n$  and that the remaining m components, that we denote as  $x^m$ , are not observed, i.e. we only observe  $x^n(1), \ldots, x^n(l)$ . Our goal is to forecast x(l+1) given the observation of  $x^n(1), \ldots, x^n(l)$ .

• This is equivalent to minimizing the following optimization problem w.r.t  $f_n, f_m$  and the the unknown m-variables required in the representer formula.

$$\min \mathcal{L} = ||f_n||_{\Gamma_1}^2 + ||f_m||_{\Gamma_2}^2 + \lambda \sum_{i=1}^N \left( (f_n(x_i^n, x_i^m) - x_{i+1}^n)^2 + (f_m(x_i^n, x_i^m) - x_{i+1}^m)^2 \right) + (f_m(x_i^n, x_i^m) - x_{i+1}^m)^2 + ($$

• Let  $A = (x_2^n, \cdots, x_{l+1}^n)$ ,  $B = (x_2^m, \cdots, x_{l+1}^m)$ ,  $C = (\dots, (x_i^n, x_i^m), \dots)$ . The minimizers of the loss  $\mathcal{L}$  are  $f_n(\cdot) = \Gamma_1(\cdot, C)(\Gamma_1(C, C) + \lambda^{-1}I_d)^{-1}A$ ,  $f_m(\cdot) = \Gamma_2(\cdot, C)(\Gamma_2(C, C) + \lambda^{-1}I_d)^{-1}B$  which leads to the following reduced optimization problem

$${\rm min}_B A^T (\Gamma_1(C,C) + \lambda^{-1} I_d)^{-1} A + B^T (\Gamma_2(C,C) + \lambda^{-1} I_d)^{-1} B$$

Consider the Lorenz system

$$\begin{aligned} \dot{x} &= \sigma(y-x), \\ \dot{y} &= x(\rho-z)-y, \\ \dot{z} &= xy-\beta z \end{aligned}$$

with  $\sigma = 10$ ,  $\rho = 28$ ,  $\beta = \frac{8}{3}$ . First, we consider the case where we have access to the x and y variables but not z.

We follow the following steps: i.) find the auxiliary variable  $z_a$ , ii.) use kernel flows to learn the parameters of the kernel

$$\begin{split} K_{\theta}(x,y) = &\theta_{1}^{2} \exp\left(\frac{-\|x-y\|_{2}^{2}}{2\theta_{0}^{2}}\right) + \theta_{3}^{2} \left(x^{\top}y + \theta_{2}^{2}\right)^{2} + \theta_{6}^{2} \left(\theta_{4}^{2} + \theta_{5}^{2}\|x-y\|_{2}^{2}\right)^{-\frac{1}{2}} + \theta_{9}^{2} \left(\theta_{8}^{2} + \|x-y\|_{2}^{2}\right)^{-\theta_{7}} + \\ &\theta_{11}^{2} \left(1 + \frac{\|x-y\|_{2}^{2}}{\theta_{10}^{2}}\right)^{-1} + \theta_{12}^{2} \max\left(0, 1 - \frac{\|x-y\|_{2}^{2}}{\theta_{13}^{2}}\right) + \theta_{14}^{2} \exp\left(\frac{-\|x-y\|_{2}}{2\theta_{15}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{17}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\|x-y\|_{2}^{2}}{\theta_{19}}\right) + \theta_{20}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{22}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\|x-y\|_{2}^{2}}{\theta_{19}}\right) + \theta_{20}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{22}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\|x-y\|_{2}^{2}}{\theta_{19}}\right) + \theta_{20}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{22}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\|x-y\|_{2}^{2}}{\theta_{19}}\right) + \theta_{20}^{2} \exp\left(-\frac{-\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{22}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{18}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) \exp\left(-\frac{\sin^{2} \left(\pi\|x-y\|_{2}^{2}/\theta_{21}\right)}{\theta_{19}^{2}}\right) + \\ &\theta_{16}^{2} \exp\left(-\frac{\sin^{2} \left(\pi\|x$$

Boumediene Hamzi

We generate 200 data points using initial conditions x(0) = 0, y(0) = 0, z(0) = 0, and sampling time  $t_s = 0.01$ , and we use gradient descent with step size  $\eta = 10^{-7}$  to solve the optimization problem to find the auxiliary variable  $z_a$ .

For prediction, we started with a time delay  $\tau^{\dagger} = 3$  but the results were poor. By increasing the time delay to  $\tau^{\dagger} = 4$ , the results improve and are in the figures below.

• Consider a kernel of the form

$$K_{\beta,\theta}(x,y) = \sum_{i=1}^{m} \beta_i^2 k_i(x,y;\theta)$$

• Sparsify  $K_{\beta,\theta}$  by L1 regularization

$$\mathcal{L}(\beta, \theta) = \arg\min_{\beta, \theta} 1 - \frac{y_c^\top K_{\beta, \theta}^{-1} y_c}{y_b^\top K_{\beta, \theta}^{-1} y_b} + \lambda \|\theta\|_1$$

• We apply it to a database of 131 chaotic dynamical systems.

#### Sparse Kernel Flows for Learning Chaotic Dynamics

#### We use the following kernel

$$\begin{split} K(x,y) = &\theta_1^2 \exp\left(\frac{-\|x-y\|_2^2}{2\beta_1^2}\right) + \theta_2^2 \left(x^\top y + \beta_2^2\right)^2 + \theta_3^2 \left(\beta_3^2 + \beta_4^2 \|x-y\|_2^2\right)^{-\frac{1}{2}} + \theta_4^2 \left(\beta_6^2 + \|x-y\|_2^2\right)^{-\beta_5} \\ &+ \theta_5^2 \left(1 + \frac{\|x-y\|_2^2}{\beta_7^2}\right)^{-1} + \theta_6^2 \max\left(0, 1 - \frac{\|x-y\|_2^2}{\beta_8^2}\right) \\ &+ \theta_7^2 \exp\left(\frac{-\sin^2 \left(\pi \|x-y\|_2^2/\beta_9\right)}{\beta_{10}^2}\right) \exp\left(-\frac{\|x-y\|_2^2}{\beta_{11}}\right) + \theta_8^2 \exp\left(\frac{-\sin^2 \left(\pi \|x-y\|_2^2/\beta_{12}\right)}{\beta_{13}^2}\right) \\ &+ \theta_9^2 \exp\left(\frac{-\|x-y\|_2}{2\beta_{14}^2}\right) + \theta_{10}^2 \left(\beta_{15}^2 + \beta_{16}^2 \|x-y\|_2\right)^{-\frac{1}{2}} + \\ &\theta_{11}^2 \left(\beta_{18}^2 + \|x-y\|_2\right)^{-\beta_{17}} + \theta_{12}^2 \left(1 + \frac{\|x-y\|_2}{\beta_{19}^2}\right)^{-1} + \theta_{13}^2 \max\left(0, 1 - \frac{\|x-y\|_2}{\beta_{20}^2}\right) \\ &+ \theta_{14}^2 \exp\left(\frac{-\sin^2 \left(\pi \|x-y\|_2/\beta_{21}\right)}{\beta_{22}^2}\right) \exp\left(-\frac{\|x-y\|_2}{\beta_{23}}\right) \\ &+ \theta_{15}^2 \exp\left(\frac{-\sin^2 \left(\pi \|x-y\|_2/\beta_{24}\right)}{\beta_{25}^2}\right) \end{split}$$

MLDS in RKHS

• We'll use the following Gabor wavelet as basis to build the reproducing kernel :

$$G_{\tau,\omega,\theta}(t) := \left(\frac{2}{\pi^3}\right)^{\frac{1}{4}} \sqrt{\frac{\omega}{\alpha}} \cos(\omega(t-\tau) + \theta) e^{-\frac{\omega^2(t-\tau)^2}{\alpha^2}}, \quad t,\tau,\theta \in \mathbb{R} \ \omega, \alpha > 0$$

This wavelet allows only to recognize modes of the form  $t\to \cos(\omega(t-\tau)+\theta)$  "à la Fourier series".

• In our context, we extend these wavelets to detect signals of the form  $t \to y(\omega(t-\tau) + \theta)$  for  $2\pi$ -periodic signal  $y \in L^2([0, 2\pi])$ . This can be done using

$$\chi_{y;\tau,\omega,\theta}(t) := (\frac{2}{\pi^3})^{\frac{1}{4}} \sqrt{\frac{\omega}{\alpha}} \mathsf{y}(\omega(t-\tau)+\theta) e^{-\frac{\omega^2(t-\tau)^2}{\alpha^2}}, \quad t,\tau,\theta \in \mathbb{R} \ \omega,\alpha > 0$$

Given  $\chi_{\rm r}$  we construct the Gram matrix whose entries are

$$K_{y;\tau,\omega,\theta}(s,t) := \chi_{y;\tau,\omega,\theta}(s)\chi_{y;\tau,\omega,\theta}(t), \quad s,t \in [0,1]$$

• The reproducing kernel  $K_y$  associated to y, we integrate  $K_{y;\tau,\omega,\theta}(s,t)$  w.r.t  $\tau,\omega,\theta$  over their domain of definition :

$$K_{y}(s,t) = \int_{\theta_{\min}}^{\theta_{\max}} \int_{\omega_{\min}}^{\omega_{\max}} \int_{\tau_{\min}}^{\tau_{\max}} K_{y;\tau,\omega,\theta}(s,t) d\tau \, d\omega \, d\theta, \quad s,t \in [0,1]$$

 $\bullet$  For stochastic van der Pol, the function y and the corresponding kernel are

Figure: The function y used to build the kernel k(s,t) (left), Projection on the s-axis of the plot of the kernel  $K_G(s,t)$  from vs. kernel  $K_{\chi}(s,t)$ =(right) =  $\Im$

イロト イヨト イヨト

#### Consider a dynamical system

$$\dot{x} = f(x) = Fx + \bar{f}(x)$$

of large dimension n, and  $F = \frac{\partial f}{\partial x}(x)|_{x=0}$ . Suppose x = 0 is an equilibrium, i.e. f(0) = 0.

- Goal: Analyze the stability of this equilibrium.
- If F has all its eigenvalues with negative real parts  $\Rightarrow$  The origin is asymptotically stable.
- If F has some eigenvalues with positive real parts  $\Rightarrow$  The origin is unstable.

• If  $\sigma(F) \leq 0$  (some eigenvalues of F are with zero real parts with the rest of the eigenvalues having negative real parts): The linearization fails to determine the stability properties of the origin.

After a linear change of coordinates, we have

$$\dot{x}_1 = F_1 x_1 + \bar{f}_1(x_1, x_2) \dot{x}_2 = F_2 x_2 + \bar{f}_2(x_1, x_2)$$

where  $\sigma(F_1) = 0$  and  $\sigma(F_2) < 0$ .

• Intuitively, we expect the stability of the equilibrium to only depend on the nonlinear terms  $\bar{f}_1(x_1, x_2)$ . The center manifold theorem correctly formalizes this intuition.

• A center manifold is an invariant manifold,  $x_2 = \theta(x_1)$ , tangent to the  $x_1$  directions at x = 0.

Since

$$\dot{x}_1 = F_1 x_1 + \bar{f}_1(x_1, x_2) \dot{x}_2 = F_2 x_2 + \bar{f}_2(x_1, x_2)$$

and  $x_2 = \theta(x_1)$ , we deduce that  $\theta$  satisfies the PDE

$$F_2\theta(x_1) + \bar{f}_2(x_1,\theta(x_1)) = \frac{\partial\theta}{\partial x_1}(x_1) \Big(F_1x_1 + \bar{f}_1(x_1,\theta(x_1))\Big).$$

• The Center Manifold Theorem ensures that there are smooth solutions to this PDE.

The center dynamics is the dynamics on the center manifold,

$$\dot{x}_1 = F_1 x_1 + \bar{f}_1(x_1, \theta(x_1)).$$

• Center Manifold Theorem: The equilibria  $x_1 = 0, x_2 = 0$  of the original dynamics is locally asymptotically stable iff the equilibria  $x_1 = 0$  of the center dynamics is locally asymptotically stable.

- After solving the PDE, this reduces the problem to analyzing the nonlinear stability of a lower dimensional system.
- Our Contributions: kernel methods to approximate the center manifold,
- a data-based version of the center manifold theorem.
• Let  $\hat{\theta}$  be an approximant of the center manifold  $\theta$ . Given the constraints  $\theta(0) = 0$  and  $D_x \theta(0) = 0$ , we use a generalized version of the representer theorem and write

$$\hat{\theta}(x) = \sum_{i=1}^{N+1} k(x, x_i) \alpha_i + \sum_{i=1}^m \partial_i^{(2)} k(x, 0) \beta_i,$$

• ( $\Rightarrow$ ) Under certain conditions, we prove that if the equilibrium  $x_1 = 0$  of

$$\dot{x}_1 = F_1 x_1 + \bar{f}_1(x_1, \hat{\theta}(x_1)).$$

is asymptotically stable then the equilibrium  $x_1 = 0$ ,  $x_2 = 0$  of the full order dynamics is asymptotically stable ((asymptotic) stability-preserving property- in one direction at least, second direction is still missing).

• We also prove that  $||x_{1,\theta}(t) - x_{1,\hat{\theta}}(t)||$  is bounded.

#### Numerical Experiments: Example 1

• We consider the 2-dimensional system

$$\dot{x} = f_1(x, y) = xy$$
  
 $\dot{y} = f_2(x, y) = -y - x^2$ 
(1)

• Analytically, the center manifold is  $y = -x^2 + O(x^3)$ .

• We generate the training data by solving the system with an implicit Euler scheme for initial time  $t_0 = 0$ , final time T = 1000 and with the timestep  $\Delta t = 0.1$ . We initiate the numerical procedure with initial values  $(x_0, y_0) \in \{\pm 0.8\} \times \{\pm 0.8\}$  and store the resulting data pairs in X and Y after discarding all data whose x-values are not contained in the neighborhood [-0.1, 0.1] which results in N = 38248 data pairs. We use the kernels  $k_1(x, y) := (1 + xy/2)^4$  and  $k_2(x, y) = e^{-(x-y)^2/2}$ .

#### Numerical Experiments: Example 1

#### **Construction of Lyapunov Functions from Data**

Boumediene Hamzi

MLDS in RKHS

ロ ▶ ◀ ⓓ ▶ ◀ 重 ▶ ◀ 重 ▶ 重 ዏ ៚ 3rd Symp. on MLDS, Fields Inst., 09/2022

- We will consider a nonlinear ODE  $\dot{x} = f(x)$ ,  $x \in \mathbb{R}^n$  and assume that f is not known but  $x(t_i)$ ,  $i = 1, \dots, N$ , are known.
- We approximate f from  $x(t_i)$ ,  $i = 1, \dots, N$ .
- We find a Lyapunov function  $\hat{V}$  for  $\hat{f}$ .
- We prove that  $\hat{V}$  is also a Lyapunov function for f.

#### Lyapunov Functions

- Consider the system of ODEs  $\Sigma$ :  $\begin{cases} \dot{x} = f(x), \\ x(0) = \xi \end{cases}$  with  $x \in \mathbb{R}^n$ ,
- $f \in C^{\sigma}(\mathbb{R}^n, \mathbb{R}^n)$  where  $\sigma \ge 1$ ,  $n \in \mathbb{N}$ . Flow  $S_t \xi := x(t)$ , solution of  $\Sigma$ .
- Assumptions
  - 0 is an equilibrium (f(0) = 0)
  - 0 is exponentially asymptotically stable (real parts of all eigenvalues of Df(0) are negative)
- Definition (Basin of Attraction) The basin of attraction of 0 is

$$\mathcal{A} := \{ \xi \in \mathbb{R}^n | S_t \xi \to_{t \to \infty} 0 \}$$

• The basin of attraction  $\mathcal{A}$  can be determined using Lyapunov functions.

### Theorem (Lyapunov 1893)

Let  $V:\mathbb{R}^n\to\mathbb{R}^+$ ,  $K\subset\mathbb{R}^n$  a compact set.

▶ V decreases along solutions, i.e. (if V is smooth)

$$V'(x) = \frac{d}{dt} V(x(t))|_{t=0} = \nabla V(x) \cdot f(x) < 0$$

for all  $x \in K \setminus \{0\}$  ( V' is the orbital derivative = derivative along the solution )

• K is sublevel set of V, i.e.  $K = \{x \in \mathbb{R}^n | V(x) \le R\}.$ Then  $K \subset \mathcal{A}$ . • "Converse Theorems" (Massera 1949) etc. - but not constructive ! • Theorem (Existence of V, Bhatia) Let  $f \in C^{\sigma}$ ,  $\sigma \ge 1$ , 0 exponentially stable equilibrium. Then there exists  $V \in C^{\sigma}(\mathcal{A}, \mathbb{R})$  with

$$V'(x) := \nabla V(x) \cdot f(x) = -||x||^2$$
 for all  $x \in \mathcal{A}$ 

The Lyapunov function V is uniquely defined up to a constant. • Idea:  $V(x) = \int_0^\infty ||S_t x||^2 dt$ .

- Giesl proposed an algorithm to approximate Lyapunov functions using radial basis functions.
- Error estimates for this approach have been proved by Giesl and Wendland.
- The method is based on finding an approximate solution of a first-order linear PDE:

$$LV(x) = -||x||^2$$
  $(LV(x) = -p(x)$  with  $p(x) > 0$ )

with  $LV := V'(x) := \nabla V(x) \cdot f(x)$ .

#### Computation of Lyapunov Functions (Giesl, 2007)

• Theorem (Giesl, 2007)

Consider  $\dot{x} = f(x)$  with  $f \in C^{\sigma}(\mathbb{R}^n, \mathbb{R}^n)$  and let  $x_0$  be an equilibrium such that all eigenvalues of  $Df(x_0)$  have a negative real part. Let  $p(x) \in C^{\sigma}(\mathbb{R}^n, \mathbb{R})$  satisfy the following conditions: **a.**) p(x) > 0 for  $x \neq x_0$ , **b.**)  $p(x) = O(||x - x_0||_2^{\eta})$  with  $\eta > 0$  for  $x \to x_0$ , **c.**) For all  $\epsilon > 0$ , p has a lower positive bound on  $\mathbb{R}^n \setminus B(x_0, \epsilon)$  where  $B(x_0, \epsilon)$  is a the ball centered at  $x_0$  of radius  $\epsilon$ . Then there exists a Lyapunov function  $V_1 \in C^{\sigma}(A(x_0), \mathbb{R})$  such that

 $V_1(x_0) = 0$  and

$$LV_1(x) = f_1(x) := -p(x), \text{ for all } x \in A(x_0),$$

where  $A(x_0)$  is the basin of attraction of  $x_0$ .

Algorithm: Let  $\Phi(x) = \psi_k(||x||)$  be a radial function where  $\psi_k$  is a Wendland function (compact support). Consider the grid points  $X_N = \{x_1, \dots, x_N\} \subset \mathbb{R}^n$ . Consider the following ansatz

$$V_1(x) = \sum_{k=1}^N \beta_k (\delta_{x_k} \circ L)^y \Phi(x-y),$$

where  $(\delta_{x_k} \circ L)^y$  denotes differentiation with respect to y then evaluation at  $y = x_k$ .

### Computation of Lyapunov Functions (Giesl, 2007)

By considering the interpolation conditions

$$LV_1(x_j) = LV(x_j) = f_1(x_j),$$

and by plugin in the ansatz

$$\sum_{i=1}^{N} \beta_k \underbrace{(\delta_{x_j} \circ L)^x (\delta_{x_k} \circ L)^y \Phi(x-y)}_{=a_{jk}} = LV(x_j) = f_1(x_j) =: \gamma_j,$$

one gets a system of linear algebraic equations for the  $\beta$  in  $\beta s$ :

$$A\beta = \gamma$$

where the matrix A is symmetric and positive definite.

Roumed	iene	Har	nzi
Doumed		1101	

### Estimates on Lyapunov Functions (Giesl and Wendland, 2007)

#### • Theorem(Giesl & Wendland, 2007)

Let  $\psi_k$ ,  $k \in \mathbb{N}$ , be a Wendland function and let  $\Phi(x) = \psi_k(||x||) \in C^{2k}(\mathbb{R}^n, \mathbb{R})$  be a radial basis function. Let  $f \in C^{\sigma}(\mathbb{R}^n, \mathbb{R})$  where  $\sigma \geq \frac{n+1}{2} + k$ . Then, for each compact set  $K_0 \subset A(x_0)$  there is  $C^*$  such that

$$|V'(x) - V'_1(x)| \le C^* h^\theta \text{ for all } x \in K_0,$$

where  $h := \max_{y \in K_0} \min_{x \in X_n} ||x - y||$  is the fill distance and  $\lambda = 1/2$  for k = 1 and  $\lambda = 1$  for  $k \ge 2$  (or  $\lambda = k - 1/2$ ).

- Giesl's approach assumes that the right hand side of (ODE) is known, and sampled values of f are used at chosen grid points.
- We assume the underlying system  $\Sigma$  where f is unknown but, instead, we have sampled data values  $(x_i; y_i)|_{i=1}^m$  with  $y_i = f(x_i) + \eta$ ,  $i = 1, \dots, m$  with each  $x_i \in A(\bar{x})$ , and  $\eta \in \mathbb{R}^d$  is an independent random variable drawn from a probability distribution with zero mean and variance  $\sigma^2 \in \mathbb{R}^d$ .
- Our approximation algorithm looks for suitable functions in an RKHS.
- Error estimates are derived for some RKHSes that are also Sobolev spaces.

#### Consider the nonlinear system

It can be checked that  $V(x) = x_1^2 + x_2^2$  is a Lyapunov function for the system. First, we used Algorithm 1 to approximate the right hand side of (2) with m = 400 points and  $z := (x_i, y_i)_{i=1}^m$  are such that the points  $x_i$  are equidistantly distributed over [-0.95, 0.95].

Approximation of Control Systems in Reproducing Kernel Hilbert Spaces

ロ ▶ ◀ ⓓ ▶ ◀ 重 ▶ ◀ 重 ▶ 重 ዏ ៚ 3rd Symp. on MLDS, Fields Inst., 09/2022 • Consider a linear control system

$$\begin{array}{rcl} \dot{x} &=& Ax + Bu \\ y &=& Cx \end{array},$$

where  $x \in \mathbb{R}^n$ ,  $u \in \mathbb{R}^q$ ,  $y \in \mathbb{R}^p$ , (A, B) is controllable, (A, C) is observable and A is Hurwitz.

• We define the controllability and the observability Gramians as, respectively,  $W_c = \int_0^\infty e^{At} B B^{\mathsf{T}} e^{A^{\mathsf{T}} t} dt$ ,  $W_o = \int_0^\infty e^{A^{\mathsf{T}} t} C^{\mathsf{T}} C e^{At} dt$ .

• These two matrices can be viewed as a measure of the controllability and the observability of the system.

• Consider the past energy,  $L_c(x_0)$ , defined as the minimal energy required to reach  $x_0$  from 0 in infinite time

$$L_c(x_0) = \inf_{\substack{u \in L_2(-\infty,0), \\ x(-\infty) = 0, x(0) = x_0}} \frac{1}{2} \int_{-\infty}^0 \|u(t)\|^2 dt.$$

• Consider the future energy,  $L_o(x_0)$ , defined as the output energy generated by releasing the system from its initial state  $x(t_0) = x_0$ , and zero input u(t) = 0 for  $t \ge 0$ , i.e.

$$L_o(x_0) = \frac{1}{2} \int_0^\infty \|y(t)\|^2 \, dt,$$

for  $x(t_0) = x_0$  and  $u(t) = 0, t \ge 0$ .

• In the linear case, it can be shown that

$$L_c(x_0) = \frac{1}{2} x_0^{\mathsf{T}} W_c^{-1} x_0, \quad L_o(x_0) = \frac{1}{2} x_0^{\mathsf{T}} W_o x_0.$$

 $\bullet$  Moreover,  $W_c$  and  $W_o$  satisfy the following Lyapunov equations

$$AW_c + W_c A^{\mathsf{T}} = -BB^{\mathsf{T}}, \quad A^{\mathsf{T}}W_o + W_o A = -C^{\mathsf{T}}C.$$

### Controllability and Observability Energies in Model Reduction of Linear Control Systems

• Gramians have several uses in Linear Control Theory. For example, for the purpose of model reduction.

• Balancing: find a representation where the system's observable and controllable subspaces are aligned so that reduction, if possible, consists of eliminating uncontrollable states which are also the least observable.

• More formally, we would like to find a new coordinate system such that

$$W_c = W_o = \Sigma = \mathsf{diag}\{\sigma_1, \cdots, \sigma_n\},\$$

where  $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_n \geq 0$ . If (F, G) is controllable and (F, H) is observable, then there exists a transformation such that the state space expressed in the transformed coordinates  $(TFT^{-1}, TG, HT^{-1})$  is balanced and  $TW_cT^{\top} = T^{-\top}W_oT^{-1} = \Sigma$ .

(日本)(周本)(王本)(本)(王本)

Typically one looks for a gap in the singular values {σ<sub>i</sub>} for guidance as to where truncation should occur. If we see that there is a k such that σ<sub>k</sub> ≫ σ<sub>k+1</sub>, then the states most responsible for governing the input-output relationship of the system are (x<sub>1</sub>, ..., x<sub>k</sub>) while (x<sub>k+1</sub>,..., x<sub>n</sub>) are assumed to make negligible contributions.
Although several methods exist for computing T, the general idea is to compute the Cholesky decomposition of W<sub>o</sub> so that W<sub>o</sub> = ZZ<sup>T</sup>, and form the SVD UΣ<sup>2</sup>U<sup>T</sup> of Z<sup>T</sup>W<sub>c</sub>Z. Then T is given by

$$T = \Sigma^{\frac{1}{2}} U^{\mathsf{T}} Z^{-1}.$$

# Controllability and Observability Energies for Nonlinear Systems

 $\bullet$  Consider the nonlinear system  $\Sigma$ 

$$\begin{cases} \dot{x} = f(x) + \sum_{i=1}^{m} g_i(x)u_i, \\ y = h(x), \end{cases}$$

with  $x \in \mathbb{R}^n$ ,  $u \in \mathbb{R}^m$ ,  $y \in \mathbb{R}^p$ , f(0) = 0,  $g_i(0) = 0$  for  $1 \le i \le m$ , and h(0) = 0.

Hypothesis H: The linearization of the system around the origin is controllable, observable and  $F = \frac{\partial f}{\partial x}|_{x=0}$  is asymptotically stable.

Boumediene Hamzi

MLDS in RKHS

# Controllability and Observability Energies for Nonlinear Systems

• Theorem (Scherpen, 1993) If the origin is an asymptotically stable equilibrium of f(x) on a neighborhood W of the origin, then for all  $x \in W$ ,  $L_o(x)$  is the unique smooth solution of

$$\frac{\partial L_o}{\partial x}(x)f(x) + \frac{1}{2}h^{\mathsf{T}}(x)h(x) = 0, \quad L_o(0) = 0$$

under the assumption that this equation has a smooth solution on W ( $L_o$  is a Lyapunov function). Furthermore for all  $x \in W$ ,  $L_c(x)$  is the unique smooth solution of

$$\frac{\partial L_c}{\partial x}(x)f(x) + \frac{1}{2}\frac{\partial L_c}{\partial x}(x)g(x)g^{\mathsf{T}}(x)\frac{\partial^{\mathsf{T}}L_c}{\partial x}(x) = 0, \quad L_c(0) = 0$$

under the assumption that this equation has a smooth solution  $\bar{L}_c$  on Wand that the origin is an asymptotically stable equilibrium of  $-(f(x) + g(x)g^{\mathsf{T}}(x)\frac{\partial \bar{L}_c}{\partial x}(x))$  on W. • Theorem (Scherpen) Consider system  $\Sigma$  under Hypothesis H and the assumptions in the preceding theorem. Then, there exists a neighborhood W of the origin and coordinate transformation  $x = \varphi(z)$  on W converting the energy functions into the form

$$L_c(\varphi(z)) = \frac{1}{2} z^{\mathsf{T}} z,$$

$$L_o(\varphi(z)) = \frac{1}{2} \sum_{i=1}^n z_i^2 \sigma_i(z_i)^2,$$

where  $\sigma_1(x) \ge \sigma_2(x) \ge \cdots \ge \sigma_n(x)$ . The functions  $\sigma_i(\cdot)$  are called *Hankel* singular value functions.

- In the above framework for balancing of nonlinear systems, one needs to solve (or numerically evaluate) the PDEs and compute the coordinate change  $x = \varphi(z)$ .
- However there are no systematic methods or tools for solving these equations.
- Various approximate solutions based on Taylor series expansions have been proposed Krener (2007, 2008), Fujimoto and Tsubakino (2008).
- Newman and Krishnaprasad (2000) introduce a statistical approximation based on exciting the system with white Gaussian noise and then computing the balancing transformation using an algorithm from differential topology.
- An essentially linear empirical approach, similar to Moore's empirical approach, was proposed by Lall, Marsden and Glavaski (2002).

### Computing the Controllability and Observability Energies: Linear Case

• Analytic Approach: The Gramians  $W_c$  and  $W_o$  satisfy the Lyapunov equations

$$FW_c + W_c F^{\mathsf{T}} = -GG^{\mathsf{T}},$$
  
$$F^{\mathsf{T}}W_o + W_o F = -H^{\mathsf{T}}H.$$

• Data-Based Approach: Moore showed that  $W_c$  and  $W_o$  can be obtained from the impulse responses of  $\Sigma_L$ . For instance,

$$W_c = \int_0^\infty X(t)X(t)^T dt, \quad W_o = \int_0^\infty Y^T(t)Y(t)dt$$

where X(t) is the response to  $u^i(t) = e_i$  with x(0) = 0, and Y(t) is the output response to u(t) = 0 and  $x(0) = e_i$ . Given X(t) and Y(t), one can perform PCA to obtain  $W_c$  and  $W_o$  respectively. The observability and controllability Gramians may be estimated statistically from typical system trajectories:

$$\widehat{W}_c = \frac{T}{mN} \sum_{i=1}^N X(t_i) X(t_i)^{\mathsf{T}}, \quad \widehat{W}_o = \frac{T}{pN} \sum_{i=1}^N Y(t_i) Y(t_i)^{\mathsf{T}}.$$

where  $t_i \in [0, T], i = 1, ..., N$ ,  $X(t) = [x^1(t) \cdots x^m(t)]$ , and  $Y(t) = [y^1(t) \cdots y^n(t)]^\top$  if  $\{x^j(t)\}_{j=1}^m, \{y^j(t)\}_{j=1}^n$  are measured (vector-valued) responses and outputs of the system.

### Computing the Controllability and Observability Energies for Nonlinear Systems

#### Questions

- How to compute the controllability and observability energies from data ?
- How to extend Moore's empirical approach to Nonlinear Control Systems ?
- Are there "Gramians" for Nonlinear Systems ? and in the affirmative, how to compute them from data ?
- Idea ! Use of kernel methods. A kernel based procedure may be interpreted as mapping the data, through "feature maps", from the original input space into a potentially higher dimensional Reproducing Kernel Hilbert Space where linear methods may then be used.

# Controllability and Observability Energies of Nonlinear Systems in RKHSes

• We consider a general nonlinear system of the form

$$\begin{cases} \dot{x} &= f(x, u) \\ y &= h(x) \end{cases}$$

with  $x \in \mathbb{R}^n$ ,  $u \in \mathbb{R}^m$ ,  $y \in \mathbb{R}^p$ , f(0,0) = 0, and h(0) = 0.

• Assume that the method of linear balancing can be applied to the nonlinear system when lifted into an RKHS.

• In the linear case,  $L_c(x_0) = \frac{1}{2}x_0^T W_c^{-1}x_0$  and  $L_o(x_0) = \frac{1}{2}x_0^T W_o x_0$  can be rewritten as  $L_c(x_0) = \frac{1}{2} \langle W_c^{\dagger} x_0, x_0 \rangle$  and  $L_o(x_0) = \frac{1}{2} \langle W_o x_0, x_0 \rangle$ . • In the nonlinear case, it may be tempting to write, in  $\mathcal{H}$ ,  $L_c(x) = \frac{1}{2} \langle W_c^{\dagger} h, h \rangle$  and  $L_o(x) = \frac{1}{2} \langle W_o h, h \rangle$  where  $h = \Phi(x) = K(x, \cdot)$  and  $\Phi : \mathbb{R}^n \to \mathcal{H}$ . However, there are some complications...

# Controllability and Observability Energies of Nonlinear Systems in RKHSes

We can show that

$$\hat{L}_{c}(x) = \frac{1}{2} \left\langle \left(\frac{1}{m} \mathcal{R}_{\mathbf{x}}^{*} \mathcal{R}_{\mathbf{x}} + \lambda I\right)^{-2} \frac{1}{m} \mathcal{R}_{\mathbf{x}}^{*} \mathcal{R}_{\mathbf{x}} K_{x}, K_{x} \right\rangle$$
$$= \frac{1}{2m} \left\langle \mathcal{R}_{\mathbf{x}}^{*} \left(\frac{1}{m} \mathcal{R}_{\mathbf{x}} \mathcal{R}_{\mathbf{x}}^{*} + \lambda I\right)^{-2} \mathcal{R}_{\mathbf{x}} K_{x}, K_{x} \right\rangle$$
$$= \frac{1}{2m} \mathbf{k}_{\mathbf{c}}(x)^{\mathsf{T}} \left(\frac{1}{m} K_{c} + \lambda I\right)^{-2} \mathbf{k}_{\mathbf{c}}(x),$$

where  $\mathbf{k}_{\mathbf{c}}(x) := \mathcal{R}_{\mathbf{x}} K_x = (K(x, x_{\mu}))_{\mu=1}^{Nq}$  is the Nq-dimensional column vector containing the kernel products between x and the controllability samples.

# Controllability and Observability Energies of Nonlinear Systems in RKHSes

• Similarly, letting x now denote the collection of m = Np observability samples, we can approximate the future output energy by

$$\hat{L}_{o}(x) = \frac{1}{2} \langle \widehat{W}_{o} K_{x}, K_{x} \rangle$$

$$= \frac{1}{2m} \langle \mathcal{R}_{\mathbf{x}}^{*} \mathcal{R}_{\mathbf{x}} K_{x}, K_{x} \rangle$$

$$= \frac{1}{2m} \mathbf{k}_{o}(x)^{\mathsf{T}} \mathbf{k}_{o}(x) = \frac{1}{2m} \| \mathbf{k}_{o}(x) \|_{2}^{2}$$
(3)

where  $\mathbf{k}_{\mathbf{o}}(x) := (K(x, d_{\mu}))_{\mu=1}^{Np}$  is the Np-dimensional column vector containing the kernel products between x and the observability samples.

• We consider a general nonlinear system of the form

$$\begin{cases} \dot{x} &= f(x, u) \\ y &= h(x) \end{cases}$$

with  $x \in \mathbb{R}^n$ ,  $u \in \mathbb{R}^m$ ,  $y \in \mathbb{R}^p$ , f(0,0) = 0, and h(0) = 0. We assume that the origin of  $\dot{x} = f(x,0)$  is asymptotically stable.

#### **Proposed Data-Driven Approach:**

- Assume that we can apply the method of linear balancing when the system is lifted to a high (possibly infinite) dimensional feature space.
- Carry out balancing and truncation (linear techniques) implicitly in the feature space (discard unimportant states).
- Construct a nonlinear reduced-order model by learning approximations to f, h defined directly on the reduced state space.
**Idea:** We can perform balancing/truncation in feature space by lifting the data into  $\mathcal{H}$  via  $\Phi$ , and simultaneously diagonalizing the corresponding covariance operators.

The standard empirical controllability Gramian (in  $\mathbb{R}^n$ )

$$\widehat{W}_{c} = \frac{T}{mN} \sum_{i=1}^{N} X(t_{i}) X(t_{i})^{\top} = \frac{T}{mN} \sum_{i=1}^{N} \sum_{j=1}^{m} x^{j}(t_{i}) x^{j}(t_{i})^{\top}$$

becomes

$$C_c = \frac{T}{mN} \sum_{i=1}^{N} \sum_{j=1}^{m} \left\langle \Phi\left(x^j(t_i)\right), \cdot \right\rangle_{\mathcal{H}} \Phi\left(x^j(t_i)\right)$$

for example.

# Balancing in RKHS

• "Balancing" is carried out implicitly in  $\mathcal{H}$  by simultaneous diagonalization of  $K_c$  and  $K_o$ .

• If  $K_c^{1/2}K_oK_c^{1/2} = U\Sigma^2 U^{\top}$ , we can define the aligning transformation

$$T = \Sigma^{1/2} U^{\mathsf{T}} \sqrt{K_c^{\dagger}}.$$

• The dimension of the state space is reduced by discarding small eigenvalues  $\{\Sigma_{ii}\}_{i=q+1}^{n}$ , and projecting onto the subspace in  $\mathcal{H}$  associated with the first q < n largest eigenvalues.

• This leads to the *nonlinear* state-space dimensionality reduction map  $\Pi: \mathbb{R}^n \to \mathbb{R}^q$  given by

$$\Pi(x) = T_q^{\mathsf{T}} \mathbf{k}_c(x), \quad x \in \mathbb{R}^n$$

where

$$\mathbf{k}_c(x) := \left( K(x, x^1(t_1)), \dots, K(x, x^m(t_N)) \right)^{\top}.$$

Consider the 7 - D system (Nilsson, 2009)

$$\begin{aligned} \dot{x}_1 &= -x_1^3 + u & \dot{x}_2 &= -x_2^3 - x_1^2 x_2 + 3x_1 x_2^2 - u \\ \dot{x}_3 &= -x_3^3 + x_5 + u & \dot{x}_4 &= -x_4^3 + x_1 - x_2 + x_3 + 2u \\ \dot{x}_5 &= x_1 x_2 x_3 - x_5^3 + u & \dot{x}_6 &= x_5 - x_6^3 - x_5^3 + 2u \\ \dot{x}_7 &= -2x_6^3 + 2x_5 - x_7 - x_5^3 + 4u \\ y &= x_1 - x_2^2 + x_3 + x_4 x_3 + x_5 - 2x_6 + 2x_7 \end{aligned}$$

#### **SDEs in Reproducing Kernel Hilbert Spaces**

Boumediene Hamzi

MLDS in RKHS

3rd Symp. on MLDS, Fields Inst., 09/2022

-

- Consider the stochastically excited stable dynamical control systems affine in the input  $u\in \mathbb{R}^q$ 

$$\dot{x} = f(x) + G(x)u \; ,$$

where  $G : \mathbb{R}^n \to \mathbb{R}^{n \times q}$  is a smooth matrix-valued function. We replace the control inputs by sample paths of white Gaussian noise processes, giving the corresponding stochastic differential equation (SDE)

$$dX_t = f(X_t)dt + G(X_t)dW_t^{(q)}$$

with  $W_t^{(q)}$  a q-dimensional Brownian motion. The solution  $X_t$  to this SDE is a Markov stochastic process with transition probability density  $\rho(t, x)$  that satisfies the Fokker-Planck (or Forward Kolmogorov) equation

$$\frac{\partial \rho}{\partial t} = -\langle \frac{\partial}{\partial x}, f\rho \rangle + \frac{1}{2} \sum_{j,k=1}^{n} \frac{\partial^2}{\partial x_j \partial x_k} [(GG^T)_{jk}\rho] =: L\rho \; .$$

Boumediene Hamzi

- In the context of linear Gaussian theory where we are given an n-dimensional system of the form  $dX_t = AX_t dt + BdW_t^{(q)}$ , with  $A \in \mathbb{R}^{n \times n}$ ,  $B \in \mathbb{R}^{n \times q}$ , the transition density is Gaussian.
- It is therefore sufficient to find the mean and covariance of the solution X(t) in order to uniquely determine the transition probability density.

- The mean satisfies  $\frac{d}{dt}\mathbb{E}[x] = A\mathbb{E}[x]$  and thus  $\mathbb{E}[x(t)] = e^{At}\mathbb{E}[x(0)]$ . If A is Hurwitz,  $\lim_{t\to\infty}\mathbb{E}[x(t)] = 0$ .
- The covariance satisfies  $\frac{d}{dt}\mathbb{E}[xx^T] = A\mathbb{E}[xx^T] + \mathbb{E}[xx^T]A + BB^T$ .
- Hence,  $\mathcal{Q} = \lim_{t \to \infty} \mathbb{E}[xx^{\dagger}]$  satisfies the Lyapunov system  $A\mathcal{Q} + \mathcal{Q}A^{\top} = -BB^{\top}$ . So,  $\mathcal{Q} = W_c = \int_0^\infty e^{At}BB^{\top}e^{A^{\top}t} dt$ , where  $W_c$  is the controllability Gramian, which is positive iff the pair (A, B) is controllable.

- Combining the above facts, the steady-state probability density is given by  $\rho_\infty(x)=Z^{-1}e^{-\frac12x^\top W_c^{-1}x}=Z^{-1}e^{-L_c(x)}$ 

with  $Z = \sqrt{(2\pi)^n \det(W_c)}$ .

• The preceding suggests the following key observations in the linear setting: Given an approximation  $\hat{L}_c$  of  $L_c$  we obtain an approximation for  $\rho_{\infty}$  of the form

 $\hat{\rho}_{\infty}(x) \propto e^{-\hat{L}_c(x)}$ 

• Although the above relationship between  $\rho_{\infty}$  and  $L_c$  holds for only a small class of systems (e.g. linear and some Hamiltonian systems), by mapping a nonlinear system into a suitable reproducing kernel Hilbert space we may reasonably extend this connection to a broad class of nonlinear systems.

• Assumption1: Given a suitable choice of kernel K, if the  $\mathbb{R}^d$ -valued stochastic process x(t) is a solution to the (ergodic) stochastically excited nonlinear system

$$dX_t = f(X_t)dt + G(X_t) \circ dW_t^{(q)}$$

the  $\mathcal{H}$ -valued stochastic process  $(\Phi \circ x)(t) =: X(t)$  can be reasonably modelled as an Ornstein-Uhlenbeck process

$$dX(t) = AX(t)dt + \sqrt{C}dW(t), \quad X(0) = 0 \in \mathcal{H}$$

where A is linear, negative and is the infinitesimal generator of a strongly continuous semigroup  $e^{tA}$ , C is linear, continuous, positive and self-adjoint, and W(t) is the cylindrical Wiener process.

• Assumption2: The measure  $P_{\infty}$  is the invariant measure of the OU process and  $P_{\infty}$  is the pushforward along  $\Phi$  of the unknown invariant measure  $\mu_{\infty}$  on the statespace  $\mathcal{X}$  we would like to approximate. • Assumption3: The measure  $\mu_{\infty}$  is absolutely continuous with respect to Lebesgue measure, and so admits a density. • The stationary measure  $\mu_\infty$  is defined on a finite dimensional space, so together with part (iii) of Assumption A, we may consider the corresponding density

 $\rho_{\infty}(x) \propto \exp\left(-\hat{L}_c(x)\right)$ 

#### Experiment

#### Consider the SDE $dX = -5X^5 + 10X^3 + \sqrt{2}dW$ .

# Conclusions

- We used kernel flows to approximate chaotic dynamical systems.
- We used the maximum mean discrepancy and extended kernel mode decomposition to detect critical transitions.
- We introduced estimators for the controllability/observability energies of nonlinear control systems. We used these energies to perform model approximation of nonlinear control systems using a linear technique.
- We showed that the controllability energy estimator may be used to estimate the stationary solution of the Fokker-Planck equation governing nonlinear SDEs using a linear estimate.
- We introduced a data-based approach for the construction of Lyapunov functions, Center Manifold Approximation and Center Manifold Theorem.
- These results collectively argue that working in reproducing kernel Hilbert spaces offers tools for a data-based theory of nonlinear dynamical systems.
